# Subject Index

Acenaphthalene
  Pauson–Khand reaction, 1047
Acetals, silylketene
  reaction with imines, 102
Acetamide, dimethyl-
  dimethyl acetal
    Eschenmoser rearrangement, 891
Acetic acid, methoxyphenyl-
  methyl ester
    synthesis, 1084
Acetone
  photolysis
    with 1-methylthio-1-propyne, 163
Acetone, dibenzylidene-
  Nazarov cyclization, 752
  thermal cyclization, 754
Acetone, α,α′-dibromo-
  [4 + 3] cycloaddition reactions, 603
Acetone, geranyl-
  synthesis
    *via* Carroll rearrangement, 835
    *via* Claisen rearrangement, 828
Acetone, tetrabromo-
  [4 + 3] cycloaddition reactions, 603
Acetoxymercuration
  vinylallenes
    cyclopentenone synthesis, 774
Acetoxythallation
  vinylallenes
    cyclopentenone synthesis, 774
Acetylene
  trimerization, 1145
Acetylene, bis(trimethylsilyl)-
  cycloaddition reactions, 1149
  *o*-quinodimethane precursor
    Diels–Alder reactions, 389
Acetylene, bis(trimethylstannyl)-
  cycloaddition reactions, 1149
Acetylene, *t*-butyl-
  trimerization
    palladium catalysis, 1148
Acetylene, dicyano-
  ene reactions, 6
Acetylene, diphenyl-
  photolysis
    with methyl *p*-cyanobenzoate, 163
  reaction with carbene complexes, 1089
  reaction with tetrahydropyridine carbene complexes, 1105
Acetylene, divinyl-
  dimerization, 63
Acetylene, ethoxy-
  reaction with dialkylallylboranes, 34
  reaction with diphenylketene, 732
Acetylene, phenyl-
  cocycloaddition
    3-hexyne, 1146
Acetylene, tolylsulfonyl-
  Diels–Alder reactions, 324
Acetylene, (trimethylsilyl)methoxy-
  cycloaddition reactions, 1149
Acetylenedicarbonyl chloride
  synthesis
    *via* retro Diels–Alder reaction, 552
Acetylenedicarboxylic acid
  dialkyl esters
    ene reactions, 6
    reaction with enamines, cyclobutene ring expansion, 687
  dimethyl ester
    Diels–Alder reactions, 347
Acetylenes, alkoxy-
  reaction with ketenes
    cyclobutenone synthesis, 689
Acetylenes, alkylthio-
  reaction with ketenes
    cyclobutenone synthesis, 689
Acid bromides
  alkenic
    divinyl ketones from, 777
Acid chlorides
  alkenic
    divinyl ketones from, 777
Acid halides
  aliphatic
    divinyl ketones from, 775
β-Acoradiene
  precursor
    synthesis *via* intramolecular ene reaction, 11
  synthesis
    *via* photocycloaddition, 139
β-Acorenol
  precursor
    synthesis *via* intramolecular ene reaction, 11
Acorenone
  precursor
    synthesis *via* intramolecular ene reaction, 11
  synthesis
    *via* photochemical cycloaddition, 129
Acorenone-B
  precursor
    synthesis *via* intramolecular ene reaction, 11
Acridizinium cations
  Diels–Alder reactions, 499
Acridones
  photochemical ring opening, 712
Acrolein
  [2 + 2] cycloaddition reactions, 72
    hydroxyethylene, 73
  ene reactions
    intermolecular, 3
    Lewis acid catalysis, 5
Acrolein, 2-siloxy-
  generation of oxyallyl cations

    [4 + 3] cycloaddition reactions, 597
Acrolein, 2-(trimethylsiloxy)-
  [4 + 3] cycloaddition reactions, 606
Acrolein acetals
  Diels–Alder reactions, 341
Acrylamide, cyclohexenyl-
  ene reactions
    intramolecular, 15
Acrylamide, hydrophenyl-
  magnesium salt
    intramolecular ene reactions, 15
Acrylates
  Diels–Alder reactions, 355
  ene reactions
    Lewis acid catalysis, 4
  optically active
    cycloaddition reactions with nitrile oxides, 263
  α-substituted
    ene reactions, 4
  synthesis
    *via* retro Diels–Alder reaction, 553
Acrylates, α-halo-
  ene reactions, 5
Acrylic acid
  Diels–Alder reactions
    chiral catalysis, 377
Acrylic acid, β-nitro-
  ethyl ester
    Diels–Alder reactions, 320
  methyl ester
    Diels–Alder reactions, 320
Acrylonitrile
  dimerization, 63
    stereochemistry, 67
  ene reactions
    intermolecular, 3
Acrylonitrile, 2-acetoxy-
  cycloaddition reactions, 267
Acrylonitrile, α-chloro-
  Diels–Alder reactions
    Lewis acid promoted, 339
Acryloyl chloride
  ene reactions
    thermal, 3
Acryloyl chloride, β,β-dimethyl-
  Nazarov cyclization, 778
Actinidine
  synthesis
    *via* Diels–Alder reaction, 492
Acuminatolide
  synthesis
    *via* Diels–Alder reaction, 468
Acyl halides
  methylenation
    Tebbe reagent, 1124
Acyl isocyanates
  2-azetidinones from, 104
Acyloins
  unsaturated
    ene reactions, 23
β-Acylvinyl carbocations
  Diels–Alder reactions, 502
Adamantene
  dimerization, 65
Aklavinone
  synthesis
    *via* Diels–Alder reactions, 327, 342, 393
Albene
  synthesis
    *via* [3 + 2] cycloaddition reactions, 308
Aldehydes
  acyclic
    synthesis *via* retro Diels–Alder reactions, 573
  cycloaddition with diynes
    bicyclic α-pyran synthesis, 1157
  Diels–Alder reactions, 433
  electron deficient
    Diels–Alder reactions, 431
  methylenation
    Tebbe reagent, 1123
    titanium isopropoxide, 1125
  α,β-unsaturated
    alkylation, Cope rearrangement, 789
    Diels–Alder reactions, chiral catalysis, 377, 464
    ene reactions, 5
    synthesis *via* retro Diels–Alder reactions, 553, 573
  γ,δ-unsaturated
    synthesis *via* Claisen rearrangement, 830
Aldehydes, α,β-epoxy-
  imines
    condensation to β-lactams, 96
Alder's *endo* rule
  Diels–Alder reaction, 318
Aldimines, *N*-phenylsulfonyl
  Diels–Alder reactions, 474
Aldonolactone sugars
  synthesis
    *via* Paterno–Büchi reaction, 158
Alkanes, 2-pyridyldi-
  synthesis
    *via* cocycloaddition, 1155
Alkenes
  acyclic
    Pauson–Khand reaction, 1043–1046
  2-azetidinones from, 102–108
  bridged bicyclic
    Pauson–Khand reaction, 1049–1051
  bridgehead
    cycloadditions, 64
  coupling with carbene complexes, 1084
  cyclization
    zirconium-promoted, 1164
  [2 + 2] cycloadditions
    thermal, 63–79
  cyclopropanation, 1084
  dimerizations
    *via* 1,3-diradicals, 63–67
  divinyl ketones from, 777
  electron deficient
    ene reactions, 2–6
  endocyclic
    synthesis *via* retro Diels–Alder reactions, 560
  ene reactions, 1–25
    intramolecular, 9–20
    Lewis acid catalysis, 4
  exocyclic
    regioselective synthesis, 1182
    synthesis *via* retro Diels–Alder reactions, 560
  fused bicyclic
    Pauson–Khand reaction, 1046–1049
  halogen derivatives
    Diels–Alder reactions, 327

- metathesis, 1115–1126
  - catalysts, 1116
  - functionalization, 1116
  - polymerization, 1116
- monocyclic
  - Pauson–Khand reaction, 1046–1049
- photoaddition reactions
  - with ynones, 164
- polyfluorinated
  - cycloaddition reactions with ketenimines, 113
- polymerization, 1115
- reaction with nitrile oxides, 260
- substituted
  - synthesis *via* retro Diels–Alder reaction, 553–565
- sulfur derivatives
  - Diels–Alder reactions, 324–327
- unactivated
  - photocycloaddition reactions, 145–147

Alkenes, nitro-
- Diels–Alder reactions, 320–322

Alkenes, β-sulfonylnitro-
- Diels–Alder reactions, 320

Alkenes, trialkylsilyl-
- divinyl ketones from, 777

2-Alkenoic acids, 2-alkyl-
- methyl esters
  - synthesis *via* retro Diels–Alder reaction, 553

Alkenyl complexes
- benzannulation, 1100

Alkyl fluorides
- synthesis
  - *via* Ireland silyl ester enolate rearrangement, 841

Alkylidenation
- carbonyl compounds, 1122–1126
- titanium metallacycles, 1124

Alkyl isocyanates
- 2-azetidinones from, 103

Alkyl thiocyanates
- trimerization, 1154

Alkyl triflates
- alkylation
  - carbonyl phosphine carbene complexes, 1076

Alkynes
- benzannulation
  - functionality, 1098
- Cope rearrangement, 797
- coupling with carbene complexes, 1089
- cyclization
  - zirconium-promoted, 1164
- cyclotrimerization
  - regioselectivity, 1144–1151
- divinyl ketones from, 777
- electrocyclization, 735–737
- electron deficient
  - ene reactions, 6–9
- four-membered heterocyclic compounds from, 116
- functionalized
  - synthesis *via* retro Diels–Alder reaction, 565
- internal
  - Pauson–Khand cycloadditions, 1041
- octacarbonyldicobalt complexes
  - Pauson–Khand reaction, 1037
- reactions with Fischer carbene complexes
  - alkyne concentration, 1099
  - solvents, 1099
- reaction with carbene complexes
  - regiochemistry, 1093
- trimerization
  - Pauson–Khand reaction, 1038

Alkynes, ω-cyano-
- cocycloaddition with alkynes, 1154

Alkynes, cyclopropyl-
- rearrangement, 947

Alkynes, ω-isocyanato-
- cocycloaddition with silylated alkynes, 1156

Alkynes, trifluoromethyl-
- ene reactions, 7

Alkynes, trimethylsilyl-
- ene reactions, 23

Alkynic alcohols
- divinyl ketones from
  - cyclization, 767–769

Alkynones
- silyl enol ethers
  - cyclization, 22

Alkynyl complexes
- [3 + 2] cycloaddition reactions
  - diazoalkanes, 1070

Alkynyl organometallic compounds
- [3 + 2] cycloaddition reactions, 277

Allene, 1,3-dimethyl(*t*-butyldimethylsilyl)-
- [3 + 2] cycloaddition reactions
  - with cyclohexanecarbaldehyde, 279

Allene, 1-methyl-1-(trimethylsilyl)-
- [3 + 2] cycloaddition reactions
  - with methyl vinyl ketone, 277

Allene, tetramethyl-
- laser photolysis
  - with benzophenone, 154
- photocycloaddition reactions
  - with acetone, 167

Allene, (trimethylsilyl)-
- [3 + 2] cycloaddition reactions
  - titanium tetrachloride catalyst, 277

Allenes
- addition to 3,4-dimethylcyclohexenone
  - photochemical cycloaddition, 130
- addition to octalone
  - photochemical cycloaddition, 130
- Cope rearrangement, 797
- electrocyclization, 734
- ene reactions, 9
  - intramolecular, 19
- photocycloaddition reactions, 133, 145
  - with carbonyl compounds, 167
- reactions with Fischer carbene complexes, 1107

Allenes, dienyl-
- electrocyclization, 734

Allenes, β-keto-
- synthesis
  - *via* Claisen rearrangement, 828

Allenes, vinyl-
- anthracene adduct
  - retro Diels–Alder reaction, 589
- electrocyclization, 707
- epoxidation
  - cyclopentenone synthesis, 772
- solvolysis
  - cyclopentenone synthesis, 772–775
- solvometallation
  - cyclopentenone synthesis, 774
- synthesis

    *via* electrocyclization, 708
Allenic alcohols, alkoxy-
  solvolysis
    cyclopentenone synthesis, 774
Allenic alcohols, vinyl-
  epoxidation
    cyclopentenone synthesis, 773
Allenic esters
  Diels–Alder reactions, 358
Allenoxides
  [4 + 3] cycloaddition reactions, 597
Allenyl organometallic compounds
  [3 + 2] cycloaddition reactions, 277–281
Allenyl systems
  Paterno–Büchi reaction, 165–168
Allodolicholactone
  synthesis
    *via* photoisomerizations, 231
α-Allokainic acid
  synthesis
    *via* intramolecular ene reaction, 13
Allyl acetate, 2-(trimethylsilylmethyl)-
  [4 + 3] cycloaddition reactions, 598
Allyl alcohol, 2-ethoxy-
  [4 + 3] cycloaddition reactions, 597
Allyl alcohol, 2-silylmethyl-
  [4 + 3] cycloaddition reactions, 598
Allyl bromide
  alkylation
    cyclic carbene complexes, 1076
Allyl bromide, 2-methoxy-
  generation of 2-methoxyallyl cation
    [4 + 3] cycloaddition reactions, 597
Allyl bromide, 2-siloxy-
  2-siloxyallyl cation generation
    [4 + 3] cycloaddition reactions, 603
Allyl cations
  [4 + 3] cycloaddition reactions, 601
  β-heteroatom-substituted
    [4 + 3] cycloaddition reactions, 594
Allyl cations, 2-amino-
  [4 + 3] cycloaddition reactions, 597
Allyl cations, 2-methoxy-
  [4 + 3] cycloaddition reactions, 597
Allyl cations, 2-methyl-
  [4 + 3] cycloaddition reactions, 603
Allyl cations, 2-silylmethyl-
  [4 + 3] cycloaddition reactions, 598
Allyl cations, 2-(trimethylsiloxy)-
  [4 + 3] cycloaddition reactions, 597, 606
Allyl cations, 2-trimethylsilylmethyl-
  [4 + 3] cycloaddition reactions, 598
Allyl chloride, 2-(trimethylsiloxy)-
  reaction with silver perchlorate
    generation of oxyallyl cations, 597
Allyl chlorides, siloxy-
  siloxyallyl cation generation
    [4 + 3] cycloaddition reactions, 606
Allyl halides
  generation of allyl cations
    [4 + 3] cycloaddition reactions, 597
  β-heteroatom-substituted
    [4 + 3] cycloaddition reactions, 597
Allylic alcohols
  acyclic
    synthesis *via* retro Diels–Alder reaction, 554
  cycloaddition reactions, 261
  [4 + 3] cycloaddition reactions, 598
  photocycloaddition reactions
    copper catalyzed, 147
  1,3-sigmatropic rearrangements
    oxyanion-accelerated, 1002
Allylic ethers
  photocycloaddition reactions
    copper catalyzed, 147
Allyl iodide
  reaction with chlorosulfonyl isocyanate, 105
Allyl organometallic compounds
  [3 + 2] cycloaddition reactions, 272–277
Aluminium bisphenoxides, methyl-
  Claisen rearrangement
    catalysis, 850
Aluminum, alkoxydichloro-
  catalysts
    Diels–Alder reactions, 376
Aluminum, allyl-
  metallo-ene reactions, 31
Aluminum, dialkoxy-
  chiral catalysts
    Diels–Alder reactions, 376
Aluminum, dichloromenthyl-
  catalysts
    Diels–Alder reactions, 376
Aluminum, vinyl-
  reaction with vinyloxiranes, 936
Aluminum compounds
  Claisen rearrangement
    catalysis, 850
Aluminum-ene reactions, 31–33
Amaryllidaceae alkaloids
  synthesis
    *via* Diels–Alder reactions, 323
Amides
  methylenation
    Tebbe reagent, 1124
  α,β-unsaturated
    chelated, Diels–Alder reactions, 365–367
    Diels–Alder reactions, 360–365, 464
  γ,δ-unsaturated
    stereoselective synthesis *via* Claisen rearrangement, 828
Amides, β-keto-2-[2-(trimethylsilyl)methyl]-
  cycloaddition reactions, 247
Amides, *N*-methylenium
  Diels–Alder reactions, 501
Amides, *N*-methyl-*N*-methylenium cations
  Diels–Alder reactions, 501
Aminium cation radicals
  Diels–Alder reactions, 520
Amino acids
  *N*-methylation
    retrograde Diels–Alder reaction, 552
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
Amino alcohols, alkynic
  divinyl ketones from
    cyclization, 769
Amino sugars
  synthesis
    *via* intramolecular Diels–Alder reaction, 425
Ammonium chloride
  Claisen rearrangement

    catalysis, 850
Angelicin
  synthesis, 1096, 1099
    regioselective, 1094
Anhydrides
  methylenation
    Tebbe reagent, 1124
Aniline, *N*-sulfinyl-
  [3 + 2] cycloaddition reactions
    with $\eta^1$-butynyliron complexes, 277
Anisole
  photocycloaddition reactions
    with vinylene carbonate, 653
[4 + 2] Annulation
  oxyanion-accelerated
    vinylcyclobutane rearrangement, 1020
Annulations
  two-alkyne, 1102
[10]Annulene
  disrotatory ring closure, 716
  synthesis
    *via* [6 + 4] cycloaddition, 623
[12]Annulene
  electrocyclization, 717
[16]Annulene
  disrotatory ring closure, 716
Antheridogen-An
  synthesis
    *via* vinylcyclopropane rearrangement, 1014
Anthracene, 9-cyano-
  photocycloaddition reactions
    cycloheptatriene, 636
    2,5-dimethyl-2,4-hexadiene, 636
Anthracene, 9,10-dimethyl-
  Diels–Alder reactions, 71
    acyl nitroso compounds, 419
    tetracyanoethylene, 76
Anthracenes
  [4 + 3] cycloaddition reactions, 608
  Diels–Alder reactions
    benzynes, 383
    Lewis acid promoted, 339
    selenocarbonyl dienophiles, 442
  photocycloaddition reactions
    2,5-dimethyl-2,3-hexadiene, 636
  photolyses, 637
  reaction with tetracyanoethylene
    thermochemistry, 76
  retrograde Diels–Alder reactions, 552
Anthracyclines
  synthesis, 1098
    *via* benzocyclobutene ring opening, 693
    *via* Diels–Alder reactions, 327, 375, 393
Anthracyclines, demethoxy-
  synthesis
    *via* Diels–Alder reaction, 338
Anthracyclinones
  synthesis
    *via* Diels–Alder reaction, 384
    *via* oxyanion-accelerated rearrangement, 1022
Anthranilic acid
  benzyne from *via* diazotization
    benzocyclobutene synthesis, 692
Anthranol
  retro Diels–Alder reaction, 564
Anthraquinone, bis(bromomethyl)-
  Diels–Alder reactions, 394
Anthraquinones
  synthesis
    *via* benzocyclobutene ring opening, 693
    *via* [2 + 2 + 2] cycloadditions, 1148
β-1-Apiofuranoside
  asymmetric synthesis
    *via* photocycloaddition, 185
Apiose
  synthesis
    *via* Paterno–Büchi reaction, 158
Aporphine alkaloids
  synthesis
    *via* Diels–Alder reaction, 384
    *via* photocyclization, 724
Arene–alkene photocycloaddition reactions
  [3 + 2] and [5 + 2], 645–671
  exciplex pathway, 649
  mechanism, 648–654
Arenediazocyanide
  Diels–Alder reactions, 428
Arenes
  [4 + 3] cycloaddition reactions, 608
Arenes, alkoxy-
  photocycloaddition reactions, 652
Arenes, alkyl-
  photocycloaddition reactions, 652
Aristeromycin
  synthesis
    *via* Diels–Alder reaction, 370
Arnottianamide, methyl-
  synthesis
    *via* Diels–Alder reaction, 500
σ-Aromaticity
  cyclopropanes, 900
Aromatin
  synthesis
    *via* Cope–Claisen rearrangement, 886
Artemisinin
  synthesis
    *via* Paterno–Büchi reaction, 155
Aryl complexes
  benzannulation, 1100
Aryl isocyanates
  2-azetidinones from, 103
Aspidosperma alkaloids
  synthesis
    *via* annulation, 1100
Aspidosperma alkaloids, deethyl-
  synthesis
    *via* retro Diels–Alder reactions, 581
Aspidospermidine, 6,7-dehydro-
  synthesis
    *via* Diels–Alder reaction, 372
Asteltoxin
  synthesis
    *via* photocycloaddition, 172
Asteriscanolide
  synthesis
    *via* [4 + 4] cycloaddition, 641
Asymmetric synthesis
  [3 + 2] cycloaddition reactions, 305
Aucubigenone
  synthesis
    *via* Pauson–Khand reaction, 1062
Avenaciolide

  synthesis
    *via* photocycloaddition, 171
Azaanion-accelerated rearrangements
  small rings, 1000–1004
2-Azabicyclo[2.2.*n*]alkenes
  flash vapor pyrolysis, 576
8-Azabicyclo[3.2.1]oct-6-ene
  Pauson–Khand reaction, 1051
1-Aza-1,3-butadiene, *N*-acyl-
  Diels–Alder reactions, 473
1-Aza-1,3-butadiene, 2-*t*-butyldimethylsiloxy-
  Diels–Alder reactions, 473
1-Aza-1,3-butadiene, *N*-phenylsulfonyl-
  Diels–Alder reactions, 474
1-Aza-1,3-butadiene, 2-trimethylsiloxy-
  Diels–Alder reactions, 473
2-Aza-1,3-butadiene, 3-trimethylsiloxy-
  Diels–Alder reactions, 480
Azabutadienes
  Diels–Alder reactions, 470–491
  synthesis
    *via* photocycloaddition, 161
1-Aza-1,3-butadienes
  Diels–Alder reactions, 473–480
2-Aza-1,3-butadienes
  Diels–Alder reactions, 480–484
  hetero
    Diels–Alder reactions, 485
2-Aza-1,3-butadienes, 1,3-bis(*t*-butyldimethylsiloxy)-
  Diels–Alder reactions, 480
Aza-Cope rearrangement, 877
Azacyclic systems
  synthesis
    *via* Ireland rearrangement, 843
Azadienes
  cationic
    Diels–Alder reactions, 492–501
  five-membered ring heteroaromatic
    Diels–Alder reactions, 491
  heteroaromatic
    Diels–Alder reactions, 411, 491–492
  six-membered ring heteroaromatic
    Diels–Alder reactions, 491
2-Aza-1,3-dienes
  synthesis
    *via* retro Diels–Alder reactions, 559
Aza-di-π-methane rearrangements
  photoisomerizations, 201, 220
Azafumarates
  intramolecular cyclization, 414
1-Aza-1-oxa-di-π-methane rearrangements
  photoisomerizations, 202
2-Aza-1,3-pentadiene, 1-phenyl-
  Diels–Alder reactions, 480
1-Azatrienes
  electrocyclic ring closure, 741
Azepine, *N*-ethoxycarbonyl-
  cycloaddition reactions
    dienes, 634
Azepines
  synthesis
    *via* cyclobutene ring expansion, 687
Azepines, 2,3-dihydro-
  synthesis
    *via* cyclobutene ring expansion, 687
Azepines, *N*-substituted
  dimerization
    *via* [6 + 4] cycloaddition, 634
Azetidine hydrazones
  synthesis, 110
Azetidines, 2-imino-
  synthesis
    *via* ketenimines, 113
Azetidines, vinyl-
  cycloaddition reactions, 257
Azetidinethiones
  synthesis
    *via* azetidiminium salts, 110
2-Azetidinethiones
  synthesis
    *via* imines and thioketenes, 115
Azetidinimines
  synthesis
    *via* azetidiminium salts, 110
2-Azetidiniminium salts
  synthesis
    *via* keteniminium salts, 108–113
2-Azetidinones
  synthesis
    *via* enolates and imines, 100–102
    *via* isocyanates, 102–108
    *via* ketenes and carbonyls, 90–100
    *via* lithium phenylethynolate cycloaddition, 116
Azetidinones, vinyl-
  cycloaddition reactions, 257
Azetines
  synthesis
    *via* retro Diels–Alder reactions, 581
Azetinones
  Diels–Alder reactions, 407
Aziridine, dienyl-
  radical opening, 938
  rearrangement
    transition metal catalyzed, 938
Aziridine, divinyl-
  rearrangement, 948
Aziridine, vinyl-
  photochemical rearrangements, 938
  rearrangements, 909, 937
Azirines
  cycloaddition reactions
    fulvenes, 630
  Diels–Alder reactions, 413
  rearrangement
    stereochemistry, 948
Azoalkanes
  denitrogenation, 205
Azoalkenes
  Diels–Alder reactions, 486
Azocines, 1,2-dihydro-
  synthesis
    *via* cyclobutene ring expansion, 687
Azo compounds
  acyclic
    Diels–Alder reactions, 428
  cyclic
    Diels–Alder reactions, 429
  Diels–Alder reactions, 426
Azodicarboxylates
  Diels–Alder reactions, 486
Azodicarboxylic acid
  diethyl ester

    Diels–Alder reactions, 426
Azomethane
  synthesis
    *via* retro Diels–Alder reactions, 576
Azomethine ylides
  cycloaddition reactions
    diasteroselective, 260
  reactions with benzaldehyde, 265
Azulene, 1,3-dimethyl-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 285
Azulene, hexahydro-
  synthesis
    *via* palladium-ene reaction, 50
Azulene, *cis*-4-keto-
  synthesis
    *via* cycloaddition reactions, 274
Azulene, perhydro-
  synthesis
    *via* [4 + 3] cycloaddition reactions, 598
Azulenes
  synthesis
    *via* [3 + 2] cycloaddition reactions, 285
    *via* [6 + 4] cycloaddition reactions, 626, 629
    *via* electrocyclization, 744
Azulenes, hydro-
  synthesis
    *via* Cope rearrangement, 803, 810
    *via* cycloaddition reactions, 274
    *via* [6 + 4] cycloaddition reactions, 626, 629
Azulenone, oxidoperhydro-
  synthesis
    *via* [4 + 3] cycloaddition, 609

Barbaralanes
  synthesis
    *via* [4 + 3] cycloaddition, 612
Barrelene
  flash vapor pyrolysis, 571
  photoisomerization, 204
    to semibullvalene, 194
Barrelenones
  photorearrangement, 229
Benzaldehydes
  Diels–Alder reactions, 433
  photolysis
    with 1-hexyne, 163
  reaction with azomethine ylides, 265
Benzannulation
  alkynes
    functionality, 1098
  aminohexatrienes, 720
  aryl *versus* alkenyl complexes, 1100
  carbene complexes, 1098
  [3 + 2 + 1] cycloadditions, 1093
  Diels–Alder reactions
    tandem, 1099
Benzene, cyano-
  photocycloaddition reactions, 652
Benzene, nitroso-
  Diels–Alder reactions
    with 1,2-dihydropyridine, 418
Benzene, 1,2,3,4-tetraphenyl-5,6-diethyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1146
Benzene, 1,2,4-tri-*t*-butyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1146
Benzene, 1,3,5-tri-*t*-butyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1148
Benzene, trifluoromethyl-
  photocycloaddition reactions, 652
Benzene, 1,2,4-triphenyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1148
Benzene, 1,3,5-triphenyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1148
Benzenes
  [4 + 3] cycloaddition reactions, 608
  derivatives
    synthesis *via* retro Diels–Alder reaction, 571–573
  Diels–Alder reactions
    benzynes, 383
  irradiation
    fulvene generation, 646
  photocycloaddition reactions
    dienes, 636
    furan, 637
    vinyl acetate, 667
  synthesis
    *via* cyclotrimerization of alkynes, 1144–1151
Benzil
  photolysis
    with 1-*t*-butylthio-1-propyne, 163
1*H*-Benz[*b*]azepines
  synthesis
    *via* cyclobutene ring expansion, 687
Benzobarrelene
  photoisomerization, 198
  substituted
    photoisomerizations, 210
Benzobarrelene, tetrachloro-
  synthesis
    *via* Diels–Alder reaction, 383
Benzobarrelenone
  photorearrangement, 229
Benzocarbazoles
  synthesis
    *via* thermolysis, 725
Benzocyclobutanols, 1-vinyl-
  1,3-rearrangements, 1022
Benzocyclobutene
  electrocyclization, 721
  synthesis
    *via* thermolysis of benzothiophene dioxides, 693
Benzocyclobutene, 1-acetoxy-1-methyl-
  thermolysis, 681
Benzocyclobutene, *trans*-1-acetoxy-2-phenyl-
  ring opening, 682
  synthesis
    *via* thermolysis of benzothiophene dioxides, 693
Benzocyclobutene, 1-acetyl-
  isomerization, 681
Benzocyclobutene, *trans*-1-alkoxy-2-phenyl-
  ring opening, 682
Benzocyclobutene, 1,2-dimethoxy-
  ring opening, 683
Benzocyclobutene, diphenyl-
  one-electron transfer, 77
Benzocyclobutene, 7,8-diphenyl-

  Diels–Alder reactions, 391
Benzocyclobutene, [(methoxycarbonyl)amino]-
  cycloaddition reactions
    fulvenes, 627
Benzocyclobutene, 1-methoxy-1-phenyl-
  rearrangement
    anthracene synthesis, 694
Benzocyclobutene, *trans*-1-methoxy-2-phenyl-
  ring opening, 682
Benzocyclobutene, 3-methyl
  synthesis
    *via* benzynes, 692
Benzocyclobutene, 6-methyl-
  synthesis
    *via* benzynes, 692
Benzocyclobutene, 7-methyl-
  Diels–Alder reactions, 391
Benzocyclobutene, 1-phenyl-
  ring opening, 682
Benzocyclobutene, 1-vinyl-
  isomerization, 680
Benzocyclobutenecarboxylic acid
  esters
    synthesis *via* benzyne cyclization, 692
Benzocyclobutenedione
  Diels–Alder reactions, 395
Benzocyclobutene-1,2-dione, 3-hydroxy-5-methyl-
  synthesis
    *via* cycloaddition, 693
Benzocyclobutenediones
  cycloaddition reactions
    metal catalyzed, 1202
Benzocyclobutene-1,2-diones
  anthraquinones from, 690
Benzocyclobutenes
  cycloaddition reactions
    fulvenes, 627
  electrocyclic ring opening, 1032, 1151
  *o*-quinodimethane precursors, 691–694
    Diels–Alder reactions, 386
  synthesis, 692
    *via* [2 + 2 + 2] cycloadditions, 1148, 1149
  thermolysis, 1031
Benzocyclobuten-7-ol, 7-phenyl-
  Diels–Alder reactions, 388
Benzocyclobutenols
  synthesis
    *via* benzyne, 692
    *via* intramolecular cyclization, 692
Benzocyclobutenols, 1-alkyl-1-cyano-
  ring opening
    morphinan synthesis, 694
Benzocyclobutenols, *trans*-2-aryl-
  synthesis
    *via* benzyne cyclization, 692
Benzocyclobuten-1-one, 3,6-dimethyoxy-
  synthesis
    *via* benzyne, 692
Benzocyclobutenones
  *o*-quinodimethane precursors
    Diels–Alder reactions, 388
  synthesis
    *via* benzyne, 692
Benzocyclobutenyl carbamate
  Diels–Alder reactions, 390
Benzocyclohexenes
  synthesis
    *via* [2 + 2 + 2] cycloadditions, 1149
Benzocyclononadienes
  synthesis
    *via* intramolecular ene reactions, 20
Benzocyclopentenes
  synthesis
    *via* [2 + 2 + 2] cycloadditions, 1149
Benzocyclopropene
  cycloaddition reactions
    metal catalyzed, 1199
Benzofluorene
  synthesis
    *via* thermolysis, 721
Benzofuran
  [3 + 2] cycloaddition reactions, 307
Benzofuran, 4,5,6,7-tetrahydro-
  retro Diels–Alder reaction, 579
Benzofurans, hydroxy-
  synthesis
    *via* FVP, 732
Benzofurans, tetrahydro-
  synthesis
    *via* oxyanion-accelerated rearrangement, 1018
Benzoic acid, *p*-cyano-
  methyl ester
    photolysis with diphenylacetylene, 163
Benzonitrile
  photochemical cycloadditions
    alkenes, 161
Benzonitrile oxide
  cycloaddition reactions
    fulvenes, 630
    tropones, 626
  reaction with (α-oxyallyl)silane, 262
Benzonitrile oxide, *p*-nitro-
  reaction with 3,4,4-trimethyl-1-pentene, 262
Benzonorbornadiene, 1,2-bis(trimethylsilyl)-
  photoisomerization, 204
Benzonorbornadiene, 1,2-dimethyl-
  photoisomerization, 204
Benzonorbornadiene, 6-methoxy-
  bridgehead-substituted
    photoisomerization, 204
Benzonorbornadiene, 1-methoxy-4-substituted
  photoisomerization, 203
Benzonorbornadienes
  deuteriated
    photoisomerization, 204
  photoisomerization, 197, 203, 205
  stoichiometric complexes
    with β-cyclodextrin, 210
  substituted
    photoisomerizations, 210
Benzonorcaradiene
  synthesis
    *via* photoisomerization, 212
Benzo[*c*]phenanthrenes
  synthesis
    *via* electrocyclization, 720
Benzo[*k*]phenanthridones
  synthesis
    *via* photolysis, 728
Benzophenone
  photolysis
    with 2-methylbut-1-en-3-yne, 164

    with *cis*-1,4-polyisoprene, 161
  reaction with 2-butene
    oxetane formation, 152
Benzophenone, 4-phenyl-
  photolysis, 154
2-Benzopyran-3-one
  cycloaddition reactions
    tropones, 618
Benzopyrans, dihydro-
  synthesis
    *via* benzocyclobutenes, 691
Benzoquinones
  laser photolysis
    with tetramethylallene, 154
  synthesis
    *via* cyclobutenone ring opening, 690
    *via* metal-catalyzed cycloaddition, 1202
1,4-Benzoquinones
  Diels–Alder reactions, 342, 451
    Lewis acid promoted, 339
  synthesis
    *via* metal-catalyzed cycloaddition, 1200
Benzo systems
  photoisomerization, 197
Benzo[*b*]thiophene, 4-phenyl-
  synthesis
    *via* photocyclization–oxidation, 720
Benzo[*b*]thiophene, 7-phenyl-
  synthesis
    *via* photocyclization—oxidation, 720
Benzothiophene 2,2-dioxides, 2,5-dihydro-
  thermolysis
    benzocyclobutene synthesis, 693
Benzothiophenes, hydroxy-
  synthesis
    *via* FVP, 732
Benzotricyclo[3.1.0.0$^{2,6}$]hex-3-ene
  photoisomerization, 212
*p*-Benzyne
  generation
    in thermal isomerization, 736
Benzyne, 3-fluoro-
  Diels–Alder reactions, 382
Benzyne, 3-methyl-
  Diels–Alder reactions, 381
Benzyne, tetrachloro-
  Diels–Alder reactions, 383
Benzynes
  Diels–Alder reactions, 379–385
  intramolecular trapping by carbanions, 692
Berson–Salem subjacent orbital effect
  1,3-sigmatropic rearrangements, 1009
Biacetyl
  photochemistry, 154
Bicyclic compounds
  inside–inside
    synthesis *via* ene reaction with methyl propiolate, 8
Bicyclization
  dienes, 1172
  diynes, 1171
  enynes, 1165–1170
    promoted by Group IV metals, 1169
    zirconium-promoted, 1163–1183
Bicyclo[5.*n*.0]alkanes
  functionalized
    synthesis *via* Cope rearrangement, 979–982
Bicycloalkanones
  inside–outside
    *via* photocycloaddition reactions, 137
Bicyclo[4.1.0]alkenes
  synthesis
    *via* photoisomerization, 211
Bicycloalkenes, vinyl-
  Cope rearrangement, 812–819
Bicyclo[1.1.0]butane, 1-cyano-
  cycloaddition reactions, 1186
Bicyclo[1.1.0]butane, 1-methoxycarbonyl-
  cycloaddition reactions, 1186
Bicyclo[1.1.0]butane, 1-methyl-
  cycloaddition reactions, 1186
Bicyclo[1.1.0]butanes
  cycloaddition reactions
    metal-catalyzed, 1185
Bicyclo[5.3.0]decanes
  synthesis
    *via* Cope rearrangement, 982
    *via* photocycloaddition, 669
Bicyclo[4.2.2]deca-3,7,9-triene
  dimerization, 66
Bicyclo[6.2.0]dec-2-ene
  thermolysis, 686
Bicyclo[6.4.0]dodecanes, alkyl-
  synthesis
    *via* [4 + 4] cycloaddition, 640
Bicyclo[3.2.0]hepta-3,6-diene, 1-methoxy-
  reaction with hexacarbonylpropynedicobalt complex
    Pauson–Khand reaction mechanism, 1039
Bicyclo[3.2.1]heptadienes
  synthesis
    *via* Cope rearrangement, 804
Bicyclo[3.2.0]hepta-1,4-dien-3-ones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1134
Bicyclo[2.2.1]heptane, 2-methoxycarbonyl-
  synthesis
    *via* cycloaddition of bicyclo[2.1.0]pentanes, 1186
Bicyclo[4.1.0]heptane-3,4-diones, 7-halo-
  tautomerism, 714
Bicyclo[2.2.1]heptanes
  synthesis
    *via* cycloaddition of bicyclo[2.1.0]pentanes, 1186
    *via* [3 + 2] cycloaddition reactions, 286
Bicyclo[3.2.0]heptanes
  synthesis
    *via* [4 + 4] cycloaddition, 639
Bicyclo[4.1.0]heptanes
  synthesis
    *via* photocycloaddition, 669
Bicyclo[2.2.1]heptan-2-one, 6-methyl-
  synthesis
    *via* intramolecular ene reactions, 21
Bicyclo[2.2.1]heptanones
  synthesis, 1104
    *via* intramolecular ene reactions, 21
Bicyclo[4.1.0]hept-2-ene, 7-*endo*-vinyl-
  Cope rearrangement, 991
Bicyclo[2.2.1]hept-5-enes
  thermolysis, 558
Bicyclo[3.2.0]hept-6-enes
  Pauson–Khand reaction, 1046, 1052
  rearrangement, 1016
Bicyclo[4.1.0]hept-2-enes

synthesis
  *via* photoisomerization, 196
Bicyclo[4.1.0]hept-3-enes
  photoisomerization, 196
Bicyclo[4.2.0]hept-2-enes
  thermal isomerizations
    *via* retro Diels–Alder reactions, 586
Bicyclo[4.1.0]hept-2-enes, 7-(1-alkenyl)-
  Cope rearrangement, 991
Bicycloheptenes, 7-vinyl-
  Cope rearrangement, 815
*exo*-Bicyclo[3.2.0]hept-2-en-7-ol
  rearrangement, 1016
Bicyclo[2.2.1]heptenols
  Cope rearrangement
    product aromatization, 791
Bicycloheptenols, 2-vinyl-
  oxy-Cope rearrangement, 815
Bicyclo[2.2.1]heptenones
  photoisomerizations, 224, 228
Bicyclo[4.1.0]heptenones, 7-halo-
  tautomerism, 714
Bicyclo[3.2.0]hept-7-one, 1-phenyl-
  reaction with vinyllithium, 1022
Bicyclo[3.1.0]hexanes
  synthesis
    *via* ring opening, 708
Bicyclo[3.1.0]hexan-2-ones, 6-(1-alkenyl)-
  Cope rearrangement, 987
Bicyclo[3.1.0]hexan-2-ones, 6-vinyl-
  enol derivatives
    Cope rearrangements, 804
Bicyclo[2.2.0]hex-1(4)-ene
  dimerization, 66
Bicyclo[3.1.0]hex-2-ene, 6-*endo*-vinyl-
  Cope rearrangement, 984
Bicyclo[2.2.0]hex-2-enes
  synthesis
    *via* photolysis, 737
  thermolysis, 678
Bicyclo[3.1.0]hex-2-enes, 6-(1-alkenyl)-
  Cope rearrangement, 984–991
  synthesis, 990
    *via* Cope rearrangement, 985
Bicyclo[3.1.0]hexenone
  synthesis
    *via* photolysis, 730
Bicyclo[2.2.0]hexenones, amino-
  rearrangement, 732
*cis*-Bicyclo[4.3.0]nona-2,4-diene
  photolysis, 737
*trans*-Bicyclo[4.3.0]nona-2,4-diene
  synthesis
    *via* thermal rearrangement, 716
Bicyclo[5.2.0]nona-2,8-diene
  synthesis
    *via* photoisomerization, 709
Bicyclo[3.2.2]nona-2,6-dienes
  synthesis
    *via* Cope rearrangement, 991, 993
Bicyclo[3.2.2]nona-6,8-dien-3-one
  synthesis
    *via* [4 + 3] cycloaddition, 608
Bicyclo[4.3.0]nonane
  synthesis
    *via* [3 + 2] cycloaddition reactions, 304
Bicyclo[3.2.2]nona-2,6,8-triene
  photoisomerization, 196
Bicyclo[3.2.2]non-6-en-3-one
  synthesis
    *via* Cope rearrangement, 992
Bicyclo[3.2.2]nonenone, 1-methoxy-
  bridged
    photoisomerizations, 226
Bicyclo[3.2.2]nonenones
  photoisomerizations, 225, 228
Bicyclo[2.2.2]octa-1,4-diene
  Pauson–Khand reaction, 1049
Bicyclo[2.2.2]octa-2,5-diene
  flash vapor pyrolysis, 571
Bicyclo[4.2.0]octa-2,4-diene
  tautomerism, 714
Bicyclo[2.2.2]octa-2,5-diene, 1,4-bis(methoxycarbonyl)-
  thermolysis, 571
Bicyclo[4.2.0]octadiene, 1-cyano-
  synthesis
    *via* photocycloaddition, 161
Bicyclo[3.2.1]octa-2,6-dienes
  photoisomerization, 205
  substituted
    synthesis *via* Cope rearrangement, 985–988
  synthesis
    *via* Cope rearrangement, 794, 984, 987
    *via* [4 + 3] cycloaddition reaction, 597
Bicyclo[2.2.1]octadienone
  elimination reactions, 558
Bicyclo[3.3.0]octanedione
  synthesis
    *via* photoisomerization, 233
Bicyclo[2.2.2]octanes
  synthesis
    *via* photocycloaddition, 657
Bicyclo[3.2.1]octanes
  synthesis
    *via* Cope rearrangement, 993
    *via* photocycloaddition, 657
Bicyclo[3.3.0]octanes
  synthesis
    *via* Claisen rearrangement, 833
    *via* [3 + 2] cycloaddition reactions, 290, 304
    *via* photocycloaddition, 654, 657
Bicyclo[4.2.0]octanes
  aromatization
    benzocyclobutene synthesis, 692
  synthesis
    *via* photocycloaddition, 657
Bicyclo[2.2.2]octanes, 2-*exo*-methylene-6-vinyl-
  Cope rearrangement, 815
Bicyclo[3.3.0]octan-3-one
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1131
Bicyclo[2.2.2]octanones
  synthesis
    *via* intramolecular ene reactions, 21
*cis*-Bicyclo[3.3.0]octan-2-ones
  synthesis
    *via* metal-catalyzed cycloaddition, 1192
Bicyclo[4.2.0]octa-2,4,7-triene
  tautomerism, 715
Bicyclo[4.2.0]octa-1,3,5-trienes
  *o*-quinodimethane precursors
    Diels–Alder reactions, 386

Bicyclo[2.2.2]oct-1-ene
  dimerization, 65
Bicyclo[3.3.0]oct-1-ene
  Pauson–Khand reaction, 1052
Bicyclo[3.3.0]oct-2-ene
  Pauson–Khand reaction, 1047
Bicyclo[2.2.2]oct-2-ene, 5,5-dicyanomethylene-
  photoisomerization, 196
Bicyclo[2.2.2]octene, vinyl-
  Cope rearrangement, 794
Bicyclo[2.2.2]octenes
  Pauson–Khand reaction, 1051
  synthesis
    *via* Cope rearrangement, 812
    *via* Diels–Alder reactions, 329
Bicyclo[4.2.0]oct-7-enes
  thermolysis, 678
Bicyclo[2.2.2]oct-5-en-2-one
  photoisomerizations, 200
Bicyclo[3.2.1]oct-6-en-3-one, 8-alkylidene-
  synthesis
    *via* [4 + 3] cycloaddition, 604
Bicyclo[2.2.2]octenone, 1-methoxy-
  photoisomerization, 226, 233
Bicyclooctenones
  synthesis
    *via* Cope rearrangement, 804
Bicyclo[2.2.2]octenones
  photoisomerizations, 218, 224, 228
Bicyclo[3.2.1]oct-6-en-3-ones
  synthesis
    *via* [4 + 3] cycloaddition, 603
Bicyclo[3.3.0]oct-1-en-3-ones
  synthesis
    *via* Pauson–Khand reaction, 1053, 1060
Bicyclo[2.1.0]pentanes
  cycloaddition reactions
    metal-catalyzed, 1186
  diradicals
    *via* photolytic rearrangement, 914
Bicyclo[2.1.0]pent-2-ene
  thermolysis, 678
Bicyclopropylidene
  cycloaddition reactions, 71
  dimerization, 65
  reaction with tetracyanoethylene, 78
*cis*-Bicyclo[5.4.0]undeca-8,10-diene
  synthesis
    *via* photolysis, 717
*trans*-Bicyclo [7.2.0]undeca-2,10-diene
  synthesis
    *via* electrocyclization, 717
Bicyclo[5.4.0]undecanes
  synthesis
    *via* Cope rearrangement, 815, 982
Bicyclo[4.4.1]undecanone
  synthesis
    *via* [6 + 4] cycloaddition, 624
Bicyclo[4.4.1]undecene
  dimerization, 65
  synthesis
    *via* [6 + 4] cycloaddition, 635
Bicyclo[4.4.1]undecenone
  synthesis
    *via* [6 + 4] cycloaddition, 620
Bicyclo[5.3.1]undecenone
  synthesis
    *via* Cope rearrangement, 1028
Bifunctional conjunctive reagents
  [3 + 2] cycloaddition reactions, 287
  trimethylenemethane from, 298–308
Bifurandiones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1138
Bilobalide
  synthesis
    *via* Diels–Alder reaction, 356
Binaphthols
  Diels–Alder reactions, 376
Biphenyl, 2,2′-divinyl-
  photochemistry, 728
Biphenyl, 2-(α-styryl)-
  photochemistry, 726
Biphenyl, 2-vinyl-
  photochemistry, 726
Biphenylenes
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1150
Bipyridines
  synthesis
    *via* cycloaddition, 1153
Bis-imines
  Diels–Alder reactions, 425
2,2′-Bis(methylenecyclopentane)
  Cope rearrangement, 820
Bisnorisocomene
  synthesis
    *via* Pauson–Khand reaction, 1062
Bistriazoles
  benzyne precursors
    Diels–Alder reactions, 382
Bleomycin $A_2$
  synthesis
    *via* Diels–Alder reaction, 492
Boat-like transition states
  Diels–Alder reactions
    decatrienones, 539–543
Borane, binaphthoxy-
  Diels–Alder reactions, 376
Borane, cyclopropyl-
  synthesis
    *via* boron-ene reaction, 33
Borane, triethyl-
  Lewis acid co-catalyst
    [3 + 2] cycloaddition reactions, 296
Boranes, acyloxy-
  chiral catalyst
    Diels–Alder reactions, 377–379
Boranes, dialkoxy-
  chiral catalysts
    Diels–Alder reactions, 376
Boranes, dialkylallyl-
  reaction with ethoxyacetylene, 34
Boranes, triallyl-
  ene reactions, 33
Bornane-10,2-sultam
  Diels–Alder reactions, 362
Bornyl fumarate
  photocycloaddition reactions
    stilbenes, 132
Boronates, 1,3-dienyl-
  Diels–Alder reactions, 336

Boron-ene reactions, 33
Boschnialactone
  synthesis
    *via* photoisomerizations, 230
Boschnialic acid
  synthesis
    *via* magnesium-ene reaction, 42
Bourbonene
  synthesis
    *via* photochemical cycloaddition, 124, 129
Bovine serum albumin
  monoclonal antibodies
    Claisen rearrangement, 855
Bovolide
  synthesis, 1092
Brefeldin A
  synthesis
    *via* [3 + 2] cycloaddition reactions, 308
Bridged systems
  synthesis
    *via* [2 + 3] cycloaddition reactions, 951
Brook–Claisen rearrangements
  tandem, 843
Brook rearrangement
  desulfonylation, 1014
Bunte salts
  Diels–Alder reactions, 436
1,3 Butadiene, 1-acetoxy-
  cycloaddition reactions
    tropones, 620
  Diels–Alder reactions, 376
1,3-Butadiene, 1-alkoxysilyl-
  synthesis
    *via* cyclobutanones, 677
1,3-Butadiene, 1,3-bis(trimethylsiloxy)-
  Diels–Alder reactions, 323
1,3-Butadiene, 2,3-bis(trimethylsiloxy)-
  synthesis
    *via* cyclobutenes, 684
1,3-Butadiene, 2,3-bis(trimethylsilylmethyl)-
  Diels–Alder reactions, 338
1,3-Butadiene, 1-diethylamino-
  cycloaddition reactions
    6,6-dimethylfulvene, 626
1,3-Butadiene, 1,1-dimethoxy-3-trimethylsiloxy-
  Diels–Alder reactions, 330
1,3-Butadiene, 2,3-dimethyl-
  cycloaddition reactions, 199
  [4 + 3] cycloaddition reactions, 603
  Diels–Alder reactions, 372, 380
1,3-Butadiene, 2-(*N*-dimethylaminomethyl)-3-(trimethylsilylmethyl)-
  Diels–Alder reactions, 338
1,3-Butadiene, 2-ethyldiethylamino-
  cycloaddition reactions
    fulvenes, 629
1,3-Butadiene, 2-hydroxy-
  synthesis
    *via* retro Diels–Alder reactions, 557
1,3-Butadiene, 2-methoxy-3-methyl-
  iterative rearrangements, 891
1,3-Butadiene, 2-methoxy-3-phenylthio-
  synthesis
    *via* cyclobutenes, 683
1,3-Butadiene, 1-methoxy-3-trimethylsiloxy-
  Diels–Alder reactions, 329
  [2 + 2] photocycloaddition, 1022
1,3-Butadiene, 2-methyl-
  synthesis
    *via* cycloaddition of 1-methylbicyclo[1.1.0]butane, 1186
1,3-Butadiene, 2-methyl-4-trimethylsiloxy-
  Diels–Alder reactions, 376
1,3-Butadiene, 1-phenyl-4-(2′-thienyl)-
  photocyclization–oxidation, 720
1,3-Butadiene, 2-[(phenylthio)methyl]-
  Diels–Alder reactions, 338
1,3-Butadiene, 1-silyl-
  Diels–Alder reactions, 335
1,3-Butadiene, 2-tributylstannyl-
  Diels–Alder reactions, 335
1,3-Butadiene, 2-triethylsilyl-
  Diels–Alder reactions, 335
1,3-Butadiene, 2-(trimethylsilylmethyl)-
  Diels–Alder reactions, 337, 338
1,3-Butadiene, 1-trimethylsiloxy-
  cycloaddition reactions
    tropones, 620
  cyclodimerization
    [4 + 4] cycloaddition, 641
1,3-Butadiene, 2-trimethylsiloxy-
  Diels–Alder reactions, 320, 329
1,3-Butadiene-2,3-dicarbonitrile
  synthesis
    *via* retro Diels–Alder reaction, 566
1,3-Butadiene-2,3-dicarboxylic acid
  synthesis
    *via* retro Diels–Alder reaction, 565
1,3-Butadienes
  cyclization, 675
  cycloaddition reactions
    tropones, 618
  [4 + 3] cycloaddition reactions, 603
  dimerization, 63
    *via* nickel-ene reaction, 56
  photocycloaddition reactions
    benzene, 636
  substituted acyclic
    synthesis *via* retro Diels–Alder reaction, 565
1,3-Butadienes, alkoxy-
  Diels–Alder reactions, 329
1,3-Butadienes, 4-alkyl-2-amino-4-(substituted amino)-1,1,3-tricyano-
  synthesis
    *via* retro Diels–Alder reaction, 566
1,3-Butadienes, 2-methoxy-1-(phenylthio)-
  Diels–Alder reactions, 333
1,3-Butadienes, 1-(phenylthio)-
  Diels–Alder reactions, 333
1,2-Butadienoic acid
  methyl ester
    reaction with *C*-methyl-*N*-phenylnitrone, 255
2,3-Butadienoic acid
  esters
    ene reactions, 9
1,2,3,4-Butanetetracarboxylic acid
  synthesis
    *via* photolysis, 723
Butatriene
  synthesis
    *via* retro Diels–Alder reaction, 589
2-Butenal, 2-methyl-

Diels–Alder reactions, 378
2-Butene
  ene reactions, 2
*cis*-2-Butene
  cyclobutanones from, 1087
2-Butene, 1-bromo-
  synthesis
    *via* 1,3-butadiene, 903
1-Butene, 3,3-dimethoxy-2-methyl-
  iterative rearrangements, 892
1-Butene, 3,3-dimethyl-
  Pauson–Khand cycloaddition, 1041
2-Butene, 2,3-dimethyl-
  ene reactions
    Lewis acid catalysis, 4
  photochemical cycloadditions
    benzonitrile, 161
2-Butene, 2-methyl-
  ene reactions
    Lewis acid catalysis, 4
  photolysis
    with benzonitrile, 161
1-Butene, 2,3,3-trimethyl-
  deuterated
    ene reactions, 2
3-Butene-1,2-diol, isopropylidene-
  reaction with (ethoxycarbonyl)formonitrile oxide, 262
But-1-en-3-yne, 2-methyl-
  photolysis
    with benzophenone, 164
2-Butyne
  reaction with iron carbene complexes, 1089
1-Butyne, 3,3-dimethyl-
  trimerization
    rhodium catalysis, 1146
1-Butyn-3-ol, 3-methyl-
  trimerization
    nickel catalysis, 1146
3-Butyn-2-one
  [3 + 2] cycloaddition reactions
    with 1,3,3-trimethyl-1-(trimethylsilyl)allene, 278
  ene reactions
    Lewis acid catalysis, 8
  photolysis
    with isobutene, 164
Butyric acid, 3-hydroxy-
  esters
    reaction with imines, 102
Butyric acid, triisopropylsiloxy-
  cycloaddition with imines, 99
γ-Butyrolactone, 2-amino-
  synthesis, 1080
Butyrolactone, menthyloxy-
  Diels–Alder reactions, 371
γ-Butyrolactones
  synthesis
    *via* [3 + 2] cycloaddition reactions, 297
    *via* metal-catalyzed cycloaddition, 1200
γ-Butyrolactones, 2,4-disubstituted
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1138
γ-Butyrolactones, α-methylene-
  synthesis, 1076
    *via* retro Diels–Alder reactions, 578

Caesalpinine
  synthesis
    *via* photocycloaddition, 176
Calciferol
  synthesis
    *via* precalciferol, 700
Calciferol, 1,25-dihydroxy-
  A ring
    synthesis *via* intramolecular ene reaction, 18
Calichemicin
  synthesis
    *via* electrocyclization, 736
California red scale female sex pheromone
  A1 component
    synthesis *via* ene reaction with methyl propiolate, 8
Camphenic acid
  synthesis
    *via* [4 + 3] cycloaddition, 603
Campherenone
  synthesis
    *via* [3 + 2] cycloaddition reactions, 286
Camphor
  synthesis
    *via* [3 + 2] cycloaddition reactions, 286
    *via* intramolecular ene reactions, 21
Cannabinoids
  synthesis
    *via* Diels–Alder reactions, 468
Cannabinol
  photochemical ring opening, 727
Cannabinol, hexahydro-
  synthesis
    *via* Diels–Alder reaction, 468
Cannabinol, 3-hydroxyhexahydro-
  synthesis
    *via* Diels–Alder reaction, 468
Cannabisativine, anhydro-
  synthesis
    *via* Diels–Alder reaction, 414
Cannivonine
  synthesis
    *via* Cope rearrangement, 814
Cantharidin
  synthesis
    *via* Diels–Alder reaction, 342
$\Delta^{9(12)}$-Capnellene
  synthesis
    *via* magnesium-ene reaction, 40
    *via* Nazarov cyclization, 763, 779
    *via* ring opening metathesis polymerization, 1121
    *via* Tebbe reagent, 1124
Carbacyclin
  synthesis
    *via* zirconium-promoted bicyclization of enynes, 1166
Carbamates, α-chloro-
  imines
    Diels–Alder reactions, 405
Carbamycin B
  synthesis
    *via* photoisomerization, 232
Carbanion-accelerated rearrangements
  small rings, 1004–1006
Carbapenems
  synthesis
    *via* cycloaddition with CSI, 105
    *via* Diels–Alder reactions, 407

Carbazoles
  synthesis
    *via* thermolysis, 725
Carbazoles, hydroxy-
  synthesis
    *via* FVP, 732
Carbene complexes
  alkene metathesis, 1115
  alkylation, 1075
  cleavage, 1083
  coupling reactions
    with alkenes, 1084
    with alkynes, 1089
  cumulenes, 1107
  cycloaddition
    reactions, 1065–1113
  nucleophilic substitutions, 1083
    reactions, 1067
Carbene complexes, alkyl amino-
  alkylation, 1076
Carbene complexes, alkyl pentacarbonyl-
  alkylation, 1076
  anions
    reaction with carbonyl compounds, 1076
Carbene complexes, amino-
  aldol reactions, 1080
  cycloaddition reactions, 1074
  synthesis, 1066
Carbene complexes, tetracarbonyl phosphine
  alkylation, 1076
Carbene complexes, α,β-unsaturated
  Michael additions, 1081
Carbenes, alkynyl-
  transition metal complexes
    [2 + 2] cycloaddition reactions, 1067, 1068
    cycloaddition reactions with 1,3-dienes, 1072
    ene reactions, 1075
Carbenes, cyclopropyl-
  ring enlargement
    cyclobutene synthesis, 677
Carbenes, vinyl-
  adducts
    Cope rearrangement, 804
  [4 + 3] cycloaddition reactions, 599, 604
Carbenoids, vinyl-
  [4 + 3] cycloaddition reactions, 599
Carbinols, divinyl-
  regioselective rearrangements
    *via* Claisen rearrangement, 851
Carbocations
  *o*-hydroxybenzyl
    Diels–Alder reactions, 501
Carbocycles
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841, 843
Carbocyclines
  synthesis
    *via* Pauson–Khand reaction, 1060
Carbodiimides
  cycloaddition reactions
    isocyanates, 1156
    ketenes, 99
γ-Carboline, dihydro-
  synthesis, 1109
Carbometallation
  organotransition metal compounds, 1163
Carbonates
  [3 + 2] cycloaddition reactions, 303
Carbonyl compounds
  alkylidenation, 1122–1126
  [3 + 2] cycloaddition reactions, 307
  cyclopropyl
    rearrangements, 941
  Diels–Alder reactions, 430
  *gem*-dimethylation
    Tebbe reagent, 1124
  reaction with alkyl pentacarbonyl carbene anions, 1076
Carbonyl compounds, α,β-unsaturated
  cycloaddition reactions
    metal catalyzed, 1197
  Diels–Alder reactions, 453
Carbonyl compounds, β,γ-unsaturated
  acyclic
    photoisomerizations, 220
  semicyclic
    photoisomerizations, 221
  synthesis, 941
Carboxylic acids
  alkenic
    divinyl ketones from, 776
  enantiomeric synthesis
    Claisen rearrangement, 864
  γ,δ-unsaturated
    synthesis, *via* Claisen rearrangement, 828
Carpanone
  synthesis
    *via* Diels–Alder reactions, 468
Carroll rearrangement
  ester enolates, 835
  variant of Claisen rearrangement, 834
α-Cartopterone
  synthesis
    *via* retro Diels–Alder reaction, 571
*cis*-Carveol
  Claisen–Cope rearrangement, 881
Carvone
  photochemical cycloadditions, 123
  silyl ketene acetal derivatives
    Cope–Claisen rearrangement, 886
Caryophyllene
  synthesis
    *via* photochemical cycloaddition, 124
α-Caryopterone
  synthesis
    *via* retro Diels–Alder reaction, 564
Cationic cyclizations, 751–781
CC-1065
  synthesis
    *via* Diels–Alder reaction, 492
Cedranoids
  synthesis
    *via* photoisomerization, 233
Cedrene
  synthesis
    *via* Nazarov cyclization, 779
    *via* photocycloaddition, 647, 657
Cedrenone
  synthesis
    *via* photocycloaddition, 659
Cedrenone, bromo-

  synthesis, 659
Cedrol
  synthesis
    *via* photoisomerizations, 231
Cephalosporin
  synthesis
    *via* cycloadditions of acid chlorides and imines, 92
Cerorubenic acid-III
  synthesis
    *via* Cope rearrangement, 816
Charge-accelerated rearrangements
  cyclobutanes, 1016
  cyclopropanes, 1006–1016
  small rings, 999–1033
Chelidonine
  synthesis
    *via* Diels–Alder reaction, 391
Chenodeoxycholic acid
  precursor
    synthesis *via* ene reaction with methyl acrylate, 5
Chloral
  *N*-sulfonyl imine
    Diels–Alder reactions, 402
Chlorosulfonyl isocyanate
  reaction with imines, 105
Chlorothricolide
  synthesis
    *via* Ireland rearrangement, 842
Chokol A
  enantioselective synthesis
    *via* Johnson rearrangement, 839
  synthesis
    *via* magnesium-ene reaction, 44
Cholecalciferol, 1α,25*S*,26-trihydroxy-
  synthesis, 257
5α-Cholesta-1,3-diene
  photoisomerization, 706
5β-Cholesta-1,3-diene
  synthesis
    *via* photoisomerization, 706
Cholestan-3-ones, 5-vinyl-
  pyrolysis
    intramolecular ene reaction, 21
Cholesterol, 25-hydroxy-
  precursor
    synthesis *via* ene reaction with methyl acrylate, 5
Cholesterol 3-acetate, 1α-hydroxy-
  synthesis
    *via* intramolecular photocycloaddition, 180
Cholesterol acetate, 24-oxo-
  synthesis
    *via* ene reaction, 6
Chorismate
  Claisen rearrangement
    enzymatic, 855
Chorismate mutase-prephenate dehydrogenase
  Claisen rearrangement, 855
Chromium complexes, isopropenyl-
  cycloaddition reactions
    cyclopentadiene in, 1070
Chromium complexes, naphthol tricarbonyl-
  synthesis, 1093
Chromium complexes, propynyl-
  cycloaddition reactions with cyclopentadiene, 1072
Chromium complexes, tricarbonyl(η-1,3,5-cycloheptatriene)-
  cycloaddition reactions
    dienes, 633
Chromium complexes, vinylcarbene-
  reaction with isoprene, 1070
Chrysene, 5,6,11,12-tetrahydro-
  synthesis
    *via* FVP, 725
Chrysenes
  synthesis
    *via* electrocyclization, 720
Chrysomelidial
  synthesis
    *via* [3 + 2] cycloaddition reactions, 309
Citronellal
  synthesis
    *via* Diels–Alder reaction, 468
Citronellate, orthodihydro-
  methyl ester
    Claisen rearrangement, 888
Claisen–Claisen rearrangement, 888
Claisen–Cope rearrangement, 876–884
Claisen rearrangements, 827–866
  abnormal, 834
  acyclic substrates
    remote stereocontrol, 864
    stereochemistry, 862
  alkyl substituents
    kinetics, 856
  allyl vinyl ethers, 832–834
    discovery, 827
  aromatic, 834
  arylsulfonyl carbanion-accelerated, 1004
  carbanion-accelerated, 829, 1004
  catalysis, 850
  charge-accelerated, 847–850
  competitive, 850
    with Wittig rearrangement, 851
  cyclic substrates
    remote stereocontrol, 864
    stereochemistry, 863
  elimination *vs.* rearrangement, 853
  enzymatic, 855
  ketenes, 829
  kinetics, 856
  mechanism, 856–865
  *ortho*, 834
  oxyanion-accelerated, 1000
  *para*, 834
  phosphorus stabilized anions, 847
  remote stereocontrol, 864
  ring expansion
    alkylaluminum-catalyzed, 850
  self-immolative process
    stereochemistry, intrinsic transfer, 860
  solvent effects, 854
  stereochemistry
    intrinsic transfer, 860–863
  stereocontrol, 859
  synthetic aspects, 830–855
  tandem ene reactions, 11
  transition state structures, 857
  vinylogous anomeric effect, 856
  ynamine, 836
Clavulones
  synthesis
    *via* retro Diels–Alder reactions, 562

Cloke rearrangement, 945
Cobalt, octacarbonyldi-
  catalysts
    alkyne trimerization, 1146
  Pauson–Khand reaction, 1037
Cobaltacycloheptanes
  β-hydride elimination
    1-heptene synthesis, 1141
Cobaltacycloheptenes
  β-hydride elimination
    1,6-heptadiene synthesis, 1141
Cobaltacyclopentadienes
  pyridone synthesis
    *via* [2 + 2 + 2] cycloaddition, 1155
  reactions with nitriles, 1152
  reaction with carbon disulfide
    thiopyran-2-thione synthesis, 1158
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1142
Cobalt complexes, carbene
  furans from, 1092
Cobaltocene
  pyridone synthesis
    *via* [2 + 2 + 2] cycloaddition, 1155
Cocycloaddition reactions
  alkynes, alkenes and carbon monoxide, 1037
Colchicine
  synthesis
    *via* [4 + 3] cycloaddition, 604
    *via* isomerization, 714
Compactin
  synthesis
    *via* Diels–Alder reaction, 350
Conduramine-F1
  synthesis
    *via* Diels–Alder reaction, 418
Conduritol A
  synthesis
    *via* retro Diels–Alder reactions, 564
Confertin
  synthesis
    *via* Cope rearrangement, 982
Conia reaction
  thermal intramolecular ene reactions, 20–23
σ-Conjugation
  cyclopropanes, 900
Consecutive rearrangements, 875–896
Cope–Claisen rearrangement, 884–887
Cope rearrangements, 785–822
  alkyl substitution, 789
  carbanion-accelerated, 1005
  catalysis, 798–803
  chirality
    transfer, 821
  chiral vinyl substituents
    double diastereoselection, 817
  *cis*-1,2-divinylcyclopropane, 971–996
  conformation, 794
  conjugating substituents, 789
  double bond configuration, 821
  equilibria, 789–796
  *erythro–threo* ratios, 821
  heterodivinylcyclopropane, 939
  metal catalysis, 799
  photochemical initiation, 802
  product aromatization, 790
  ring strain, 791–794
  stereospecificity, 819–822
  transition state conformation, 819, 857
Coriolin
  synthesis
    *via* [4 + 4] cycloaddition, 639
    *via* Pauson–Khand reaction, 1060
    *via* photocycloaddition, 146, 665, 666
    *via* photoisomerization, 232, 233
Coronafacic acid
  synthesis
    *via* Cope rearrangement, 791
    *via* ene reaction with methyl propiolate, 8
Corynantheoid indole alkaloids
  synthesis
    *via* Diels–Alder reactions, 467
Costunolide, dihydro-
  synthesis
    *via* Cope–Claisen rearrangement, 886
Coulson–Moffit model
  cyclopropane
    bonding, 900
Coumarins, dihydro-
  synthesis
    *via* aromatic Claisen rearrangement, 834
Crenulidine, acetoxy-
  synthesis
    *via* Claisen rearrangement, 833
Crotepoxide
  synthesis
    *via* retro Diels–Alder reactions, 563
Crotonaldehyde
  ene reactions
    Lewis acid catalysis, 6
  synthesis
    *via* retro Diels–Alder reaction, 553
Crotonic acid
  methyl ester
    reaction with 1-pyrroline 1-oxide, 256
Crotonyl chloride
  Nazarov cyclization, 778
Cubanes
  isomerizations
    metal catalyzed, 1188
  synthesis
    *via* photochemical cycloaddition, 123
Cumulenes
  coupling reactions
    carbene complexes, 1107
  synthesis
    *via* retro Diels–Alder reaction, 589
α-Cuparenone
  synthesis
    *via* [3 + 2] cycloaddition reactions, 284
    *via* [4 + 3] cycloaddition reactions, 603
Cuprates
  Claisen rearrangement, 844
Cyanamide
  trimerization, 1154
Cyanide, *t*-butyldimethylsilyl
  reaction with cyclic vinyloxiranes, 936
Cyanides, arylsulfonyl
  Diels–Alder reactions, 416
Cycloaddition reactions
  alkynes
    alkenes, 676

carbene transition metal complexes, 1065–1113
photochemical, 123–148
mechanisms, 124
small ring compounds
metal-catalyzed, 1185–1204
thermal, 239–270
transition metal catalysts, 271–312
[2 + 1 + 1] Cycloaddition reactions
cyclobutanones, 1087
[2 + 2] Cycloaddition reactions
alkenes
thermal, 63–79
carbene transition metal complexes, 1067
diastereofacial selectivity, 79
intramolecular, 67–72
thermal
stereochemistry, 79
[2 + 2 + 1] Cycloaddition reactions
cyclopentenone synthesis
Pauson–Khand reaction, 1037
[2 + 2 + 1 + 1] Cycloaddition reactions
two-alkyne annulations, 1102
[2 + 2 + 2] Cycloaddition reactions, 1129–1158
[3 + 2] Cycloaddition reactions
carbene complexes, 1070
intramolecular, 304
methylenecyclopropanes, 1188
synthons, 271
[4 + 2] Cycloaddition reactions
carbene complexes, 1070
[4 + 3] Cycloaddition reactions, 593–613
intramolecular, 609
[4 + 4] Cycloaddition reactions, 635–641
[6 + 4] Cycloaddition reactions, 617–635
1,2-Cycloalkanediols, 1,2-divinyl-
oxy-Cope rearrangement, 796
Cycloalkanes, *trans,trans*-1,2-bis(alkylidene)-
synthesis
*via* diyne bicyclization, 1171
Cycloalkanes, divinyl-
bridged
Cope rearrangements, 812–819
Cycloalkanes, 1,2-divinyl-
Cope rearrangement, 791, 803–812
Cycloalkenes
synthesis
*via* cycloadditions, 64
Cycloalkenes, 2,3-divinyl-
synthesis
*via* Cope rearrangement, 797
3-Cycloalkenes, 1-trimethylsiloxy-1-vinyl-
thermal rearrangements, 1001
3-Cycloalkenols, 1-vinyl-
oxy-Cope rearrangements, 1001
Cycloaraneosene
synthesis
*via* intramolecular ene reactions, 24
Cyclobutabenzannulation
biphenylene synthesis, 1151
Cyclobutadiene
synthesis
*via* retro Diels–Alder reaction, 568
Cyclobutane, cyclopropyl-
synthesis, 927
Cyclobutane, 1,2-dicyano-
synthesis
*via* acrylonitrile dimerization, 63
Cyclobutane, 1,1-dicyano-2-methoxy-
cleavage, 73
Cyclobutane, 1-lithio-1-selenophenyl-
synthesis
*via* cyclobutanones, 677
Cyclobutane, 1,2,3,4-tetravinyl-
Cope rearrangement, 810
Cyclobutanedione, tetramethyl-
irradiation
[4 + 3] cycloaddition reaction, 597
Cyclobutanes
alkenes from, 64
charge-accelerated rearrangements, 1016
ring formation
thermal, 63–79
strain energy, 900
synthesis
*via* photochemical cycloaddition, 123
Cyclobutanes, alkylidene-
isomerization
1-alkylcyclobutenes, 677
Cyclobutanes, aryl-
rearrangement
oxyanion-accelerated, 1018
Cyclobutanes, divinyl-
rearrangements, 1024–1030
anion-accelerated, 1027–1030
thermolysis
[4 + 4] cycloaddition, 639
Cyclobutanes, 1,2-divinyl-
Cope rearrangement, 791, 805, 821
palladium catalysts, 799
3,3-sigmatropic rearrangement, 1024
synthesis
*via* [2 + 2] cycloaddition, 1025
Cyclobutanes, vinyl-
rearrangements
azaanion-accelerated, 1023
oxyanion-accelerated, stereochemistry, 1018
thermal, 1016–1024
ring expansion
oxyanion-accelerated, 1017–1023
synthesis
*via* photoisomerization, 199
Cyclobutanols, 2-(2-furyl)-
rearrangement
oxyanion-accelerated, 1018
Cyclobutanols, phenyl-
rearrangement
oxyanion-accelerated, 1018
Cyclobutanols, 1-vinyl-
rearrangement
oxyanion-accelerated, 1022
Cyclobutanols, 2-vinyl-
rearrangement
oxyanion-accelerated, 1016–1022
Cyclobutanone, 2,3-divinyl-
synthesis
*via* cyclobutenone ring opening, 690
Cyclobutanones
annulation
in preparation of spirocyclic ketones, 921
synthesis, 951, 1087, 1107
*via* ring expansion, 919
*via* vinylcyclopropanes, 919

Cyclobutanones, 2-vinyl-
  divinyl ketones from
    cyclization, 770
  synthesis
    *via* Cope rearrangement, 805
    *via* ring expansion of cyclopropylcarbinols, 1020
Cyclobutene, 3-*t*-butyl-3-methoxy-
  isomerization, 679
Cyclobutene, *cis*-3,4-dichloro-
  synthesis
    *via* retro Diels–Alder reaction, 677
Cyclobutene, 3,3-diethyl-
  isomerization, 679
Cyclobutene, diimino-
  synthesis
    *via* diarylalkynes, 1130
Cyclobutene, 1,1-dimethoxy-
  synthesis
    *via* benzynes, 692
Cyclobutene, 3,3-dimethoxy-
  synthesis
    *via* retro Diels–Alder reaction, 677
Cyclobutene, *cis*-3,4-dimethoxy-
  synthesis and ring opening, 684
Cyclobutene, 3,3-dimethyl-
  isomerization, 679
Cyclobutene, 3,4-dimethyl-
  thermolysis, 678
Cyclobutene, dimethylene-
  synthesis
    *via* Cope rearrangement, 797
    *via* retro Diels–Alder reactions, 560
Cyclobutene, 3-ethoxy-
  ring opening, 1031
Cyclobutene, 3-ethyl-3-methyl-
  isomerization, 679
Cyclobutene, *cis*-3-methoxy-4-chloro-
  synthesis and ring opening, 684
Cyclobutene, 3-methyl-3-isopropyl-
  isomerization, 679
Cyclobutene, 3-methyl-3-propyl-
  isomerization, 679
Cyclobutene, perfluoro-
  ring opening, 680
Cyclobutene, 3-phenyl-
  ring opening, 682
Cyclobutene, vinyl-
  synthesis
    *via* ring opening, 708
Cyclobutene-3-carbaldehyde
  ring opening, 680
Cyclobutenediones
  cycloaddition reactions
    metal catalyzed, 1202–1204
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1130
Cyclobutenes
  *cis*-3,4-disubstituted
    cycloaddition reactions, 257
  [2 + 2 + 2] cycloaddition reactions, 1130
  electrocyclic ring opening, 1030
    anion-accelerated, 1032
  rearrangements, 1030–1033
  ring opening reactions, 675–694
    stereochemistry, 678
    substituent effects, 678–683
    two-carbon ring expansion, 686–688
  synthesis, 676
    *via* ene reactions with methyl propiolate, 7
  uses in synthesis, 683–688
Cyclobutenone, isopropylidene-
  synthesis
    *via* retro Diels–Alder reactions, 560
Cyclobutenone, methylene-
  synthesis
    *via* retro Diels–Alder reactions, 560
Cyclobutenones
  electrocyclic ring opening, 1025
  ring opening, 688–691
  synthesis, 676, 689, 1089
Cyclobutenones, 4-alkynyl-
  photolysis, 733
  thermolysis
    benzoquinone synthesis, 690
Cyclobutenones, amino-
  thermolysis, 732
Cyclobutenones, aryl-
  photolysis, 733
  thermal ring opening, 732
Cyclobut-2-enones, 4-aryl-4-hydroxy-
  rearrangement
    hydroquinone synthesis, 690
Cyclobutenones, vinyl-
  cleavage
    dienylketene synthesis, 689
  photolysis, 733
1,3-Cyclodecadiene
  synthesis
    *via* cyclobutene ring opening, 686
1,5-Cyclodecadiene
  Cope rearrangement, 794
    equilibrium, 809
1,6-Cyclodecadiene
  synthesis
    *via* Cope–Claisen rearrangement, 884
Cyclodecadienes
  Cope rearrangement
    palladium catalysts, 799
Cyclodecanes
  functionalized
    synthesis *via* Cope rearrangement, 796
Cyclodecapentaene
  synthesis
    *via* photolysis, 716
1,3,5-Cyclodecatriene
  irradiation, 717
  ring closure, 715
  synthesis
    *via* photoisomerization, 706
Cyclodecene
  stereoselective synthesis
    *via* [6 + 4] cycloaddition, 624
β-Cyclodextrin
  stoichiometric complexes
    with benzonorbornadiene, 210
Cyclododecatetraene
  synthesis
    *via* Cope rearrangement, 812
1,4-Cycloheptadiene
  photoisomerization, 196, 211
  synthesis
    *via* Cope rearrangement, 791, 803, 971

*cis*-1,4-Cycloheptadiene, 6,7-dimethyl-
  synthesis
    *via* Cope rearrangement, 973
Cycloheptadienes
  bridged
    synthesis *via* Cope rearrangement, 803
2,4-Cycloheptadienol
  potassium salt
    1,5-rearrangement, 1003
Cycloheptadienones
  Nazarov cyclization, 760
Cycloheptane, 1,3,5-trimethylene-
  synthesis
    *via* metal-catalyzed cooligomerization, 1195
Cycloheptanes
  functionalized
    synthesis *via* Cope rearrangement, 976–978
  synthesis
    *via* intramolecular ene reactions, 24
    *via* photocycloaddition, 657
Cycloheptanes, 1,2-divinyl-
  Cope rearrangement, 810
Cycloheptanoids
  synthesis
    *via* photocycloaddition, 670
Cycloheptanone
  synthesis
    *via* ring expansion, 907
Cycloheptatriene
  cycloaddition reactions
    dienes, 632
  photocycloaddition reactions
    9-cyanoanthracene, 636
  tautomerism, 713
2,4,6-Cycloheptatrien-1-one
  cycloaddition reactions, 618–626
Cycloheptene
  Pauson–Khand reaction, 1049
Cycloheptenes, methylene-
  synthesis
    *via* [4 + 3] cycloaddition reactions, 598
4-Cyclohepten-1-ones
  substituted
    synthesis *via* Cope rearrangement, 976
  synthesis
    *via* [4 + 3] cycloaddition, 603
1,9-Cyclohexadecadiene
  synthesis
    *via* alkene metathesis, 1119
1,2-Cyclohexadiene
  synthesis
    *via* electrocyclization, 735
1,4-Cyclohexadiene
  photoisomerization, 196
1,3-Cyclohexadiene, *cis*-5,6-dimethyl-
  synthesis
    *via* 2,4,6-octatriene electrocyclization, 702
1,3-Cyclohexadiene, *trans*-5,6-dimethyl-
  synthesis
    *via* 2,4,6-octatriene electrocyclization, 702
1,3-Cyclohexadiene, *cis*-5,6-dimethyl-1,4-diphenyl-
  photochemical ring opening, 739
1,3-Cyclohexadiene, 2,3-divinyl-
  synthesis
    *via* Cope rearrangement, 797
1,3-Cyclohexadiene, 1-methoxy-
  Diels–Alder reactions, 376
1,4-Cyclohexadiene, 1,2,4,5-tetraphenyl-
  synthesis
    *via* metal-catalyzed cycloaddition, 1197
1,3-Cyclohexadiene, 2-trimethylsiloxy-
  Diels–Alder reactions
    imines, 403
Cyclohexadiene amino acids
  synthesis
    Diels–Alder reactions, 320
1,3-Cyclohexadienecarboxylic acids
  synthesis
    *via* Diels–Alder reactions, 322
Cyclohexadienes
  Pauson–Khand reaction, 1049
  photochemical ring opening, 710
  photocycloaddition reactions
    anthracene, 636
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1142–1144
    *via* retro Diels–Alder reaction, 569
1,3-Cyclohexadienes
  [4 + 3] cycloaddition reactions, 603
  Diels–Alder reactions
    imines, 404, 408
  photoaddition reactions
    with propionaldehyde, 165
  synthesis
    *via* electrocyclization, 699–745
    *via* retro Diels–Alder reaction, 568
Cyclohexadienimines, *N*-alkyl-
  synthesis
    *via* photolysis, 731
2,4-Cyclohexadienone, 5-allyl-
  Cope rearrangement, 790
Cyclohexadienones
  annulation, 1093, 1099
  synthesis
    *via* Diels–Alder reactions, 329
2,4-Cyclohexadienones
  photo rearrangements, 223
2,5-Cyclohexadienones
  photo rearrangement, 730
2,5-Cyclohexadienones, 4,4-disubstituted
  Nazarov cyclization, 760
Cyclohexane, alkylidene-
  ene reactions
    Lewis acid catalysis, 6
Cyclohexane, α-chloronitroso-
  Diels–Alder reactions, 418
Cyclohexane, cyclopropylidene-
  cycloaddition reactions
    carbon dioxide, metal catalyzed, 1196
Cyclohexane, 1,2-dimethylene-
  [4 + 3] cycloaddition reactions, 603
  Diels–Alder reactions, 338
Cyclohexane, methylene-
  ene reactions
    Lewis acid catalysis, 4
Cyclohexane, 5-methylene-3-vinylallylidene-
  synthesis
    *via* metal-catalyzed cyclodimerization, 1190
Cyclohexanecarbaldehyde
  [3 + 2] cycloaddition reactions
    with 1,3-dimethyl(*t*-butyldimethylsilyl)allene, 279
Cyclohexanes

  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1141
    *via* ene reactions, 9
Cyclohexanes, 1,2-divinyl-
  Cope rearrangement, 794, 809, 821
Cyclohexanes, 1-vinyl-2-alkyl-
  synthesis
    *via* intramolecular ene reactions, 17
Cyclohexanes, 1-vinyl-2-alkylidine-
  synthesis
    *via* intramolecular ene reaction, 18
Cyclohexanols, 1,2-divinyl-
  Cope rearrangement, 796
Cyclohexanone, 2,6-dibromo-
  [4 + 3] cycloaddition reactions, 608
Cyclohexanone, isopropylidene-
  [3 + 2] cycloaddition reactions
    with 1-methyl-1-(trimethylsilyl)allene, 278
Cyclohexanone, 2-methyl-
  silyl enol ether
    [3 + 2] cycloaddition reactions, 282
Cyclohexanone, 4-phenylthio-
  synthesis
    *via* oxyanion-accelerated rearrangement, 1023
Cyclohexanones
  *t*-butyldimethylsilyl enol ether
    ene reactions, 1075
    2,2-disubstituted, chiral
    synthesis *via* Claisen rearrangement, 832
1,2,4-Cyclohexatriene
  synthesis
    *via* electrocyclization, 735
Cyclohexene, 1,6-dimethyl-
  epoxidation, 130
Cyclohexene, methoxy-
  cycloaddition reactions
    with benzonitrile, 161
Cyclohexenes
  [2 + 2 + 2] cycloaddition reactions, 1130
  Pauson–Khand reaction, 1049
  retrograde Diels–Alder reaction, 552
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1141
    *via* vinylcyclobutane rearrangement, 1016
Cyclohexenes, 3,5-dimethylene-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1141
Cyclohexenes, 3,6-dimethylene-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1141
Cyclohexenes, 1,2-divinyl-
  thermal cyclization, 713
3-Cyclohexenols
  synthesis
    *via* [3 + 3] annulation, 1020
2-Cyclohexenone, 2-acetyl-
  Diels–Alder reactions, 461
Cyclohexenone, 2-benzyl-3-methyl-
  alkylation
    Cope rearrangement, 789
Cyclohexenone, 4-*t*-butyl-
  photocycloaddition reactions, 130
Cyclohexenone, 3,4-dimethyl-
  addition to allene
    photochemical cycloaddition, 130
  photocycloaddition reactions, 131
Cyclohexenone, 4-isopropyl-
  photocycloaddition reactions, 130
Cyclohexenone, 2-methyl-
  [3 + 2] cycloaddition reactions, 301
Cyclohexenone, 3-methyl-
  photocycloaddition reactions, 125
Cyclohexenone, 3-nitro-
  Diels–Alder reactions, 320
Cyclohexenones
  [3 + 2] cycloaddition reactions, 301
    with $\eta^1$-butynyliron complexes, 277
  photocycloaddition reactions, 125
  synthesis
    *via* Diels–Alder reactions, 329
Cyclohexenones, 4-alkenyl-
  photocycloaddition reactions, 144
Cyclohexenones, 4-alkyl-
  photocycloaddition reactions, 142
Cyclohexenones, α-epoxy-
  synthesis
    *via* retro Diels–Alder reactions, 563
Cyclohexenones, 5-substituted
  synthesis
    *via* Diels–Alder reactions, 324
3-Cyclohexenylamines
  synthesis
    *via* azaanion-accelerated rearrangement, 1023
Cyclohexyne
  anthracene adduct
    retro Diels–Alder reaction, 589
Cyclomethylenomycin A
  synthesis
    *via* Pauson–Khand reaction, 1051
1,5-Cyclononadiene
  Cope rearrangement, 794
    equilibrium, 806
Cyclononatetraene
  thermal rearrangement, 716
1,3,5-Cyclononatriene
  electrocyclization, 702
  photoisomerization, 709
  photolysis, 737
1,3,6-Cyclononatriene
  synthesis
    *via* photoisomerization, 709
Cyclononatrienols
  Cope rearrangement, 806
Cyclononenones
  synthesis
    *via* Cope rearrangement, 796
1,3-Cyclooctadiene
  dimerization, 66
  photoaddition reactions
    with acetone, 166
*cis,cis*-1,3-Cyclooctadiene
  synthesis
    *via* Cope rearrangement, 805
Cyclooctadienes
  bridged
    synthesis *via* Cope rearrangement, 806
  synthesis
    *via* [4 + 4] cycloaddition, 639, 640
1,5-Cyclooctadienes
  bridged
    Cope rearrangement, 816
  cycloreversion reactions, 64

  dimerization, 66
  synthesis
    *via* Cope rearrangement, 791
*cis,cis*-1,5-Cyclooctadienes
  synthesis
    *via* divinylcyclobutane rearrangements, 1025
2,4-Cyclooctadienone
  dimerization, 66
Cyclooctadienones
  synthesis
    *via* cyclobutenone ring opening, 690
4*H*,5*H*,9*H*,10*H*-Cycloocta[1,2-*b*:6,5-*b'*]difuran
  synthesis
    *via* [4 + 4] cycloaddition, 639
Cyclooctanes
  fused
    synthesis *via* Cope rearrangement, 806
  synthesis
    *via* [4 + 4] cycloaddition, 639
    *via* divinylcyclobutane rearrangements, 1024
    *via* intramolecular ene reactions, 24
Cyclooctanes, 1,2-divinyl-
  Cope rearrangement, 810–812
Cyclooctatetraene
  cycloaddition reactions
    dienes, 634
  synthesis
    *via* photoisomerization, 205
  tautomerism, 715
1,3,5-Cyclooctatriene
  tautomerism, 714
Cyclooctene
  Pauson–Khand reaction, 1049
  photoaddition reactions
    with acetone, 166
  photocycloaddition reactions
    with toluene, 655
  ring opening metathesis polymerization, 1120
Cyclooctene, methylene-
  Cope rearrangement, 794
Cyclooct-5-ene, 3-methyleneallylidene-
  synthesis
    *via* metal-catalyzed cyclodimerization, 1190
Cyclooctenones
  synthesis
    *via* Cope rearrangement, 1028
Cyclopentadiene, 5-(methoxymethyl)-
  Diels–Alder reactions, 353
Cyclopentadienes
  [4 + 3] cycloaddition reactions, 603–605
  cycloaddition reactions
  isopropenyl chromium complexes, 1070
    propynyl chromium complexes, 1072
    tropones, 618, 621
  Diels–Alder reactions, 380–383, 451
    comparison of promoters, 345
    imines, 403
    Lewis acid promoted, 340
    water promoted, 344
  Pauson–Khand reaction, 1046
  retrograde Diels–Alder reactions, 552
  synthesis
    *via* [3 + 2] cycloaddition reactions, 278, 1090
    *via* retro Diels–Alder reaction, 568
1,3-Cyclopentadienes, 1-amino-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1131
1,3-Cyclopentadienes, C-5 substituted
  Diels–Alder reactions, 347
Cyclopentadienone, 2,5-di-*t*-butyl-3,4-dimethyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1135
Cyclopentadienone, 2,5-dimethoxycarbonyl-3,4-diphenyl-
  cycloaddition reactions
    cyclooctatetraene, 634
    *N*-ethoxycarbonylazepine, 634
Cyclopentadienone, 2,5-dimethyl-3,4-diphenyl-
  cycloaddition reactions
    cycloheptatriene, 632
    fulvenes, 626
    tropones, 620, 622
Cyclopentadienone, tetra-*t*-butoxy-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1133
Cyclopentadienone, tetrakis(dimethylamino)-
  iron complex
    synthesis, 1133
Cyclopentadienone, tetrakis(trifluoromethyl)-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1134
Cyclopentadienone, tetraphenyl-
  [4 + 3] cycloaddition reactions, 604
Cyclopentadienone epoxides
  synthesis
    *via* retro Diels–Alder reactions, 561
Cyclopentadienones
  [4 + 3] cycloaddition reactions, 603
  substituted
    synthesis *via* retro Diels–Alder reaction, 568
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1133–1135
Cyclopentadienones, bis(trimethylsilyl)-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1134
Cyclopentadienylmethyl metal complexes
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1147
Cyclopentane, dimethylene-
  synthesis, 1107
Cyclopentane, 1,3-dimethylene-
  synthesis
    *via* metal-catalyzed cooligomerization, 1195
Cyclopentane, 1,2-dimethylene-3,3,4,4,5,5-hexamethyl-
  [4 + 3] cycloaddition reactions, 600
Cyclopentane, 2,2-dimethylmethylene-
  synthesis
    *via* metal-catalyzed cycloaddition, 1190
Cyclopentane, divinyl-
  synthesis
    *via* palladium-ene reaction, 48
Cyclopentane, ethylidene-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 290
Cyclopentane, 3-methoxycarbonylmethylene-
  synthesis
    *via* metal-catalyzed cycloaddition, 1190
Cyclopentane, 2-methylvinyl-
  synthesis
    *via* magnesium-ene reaction, 38
    *via* nickel-ene reaction, 56

Cyclopentane, sulfonyl(methylene)-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 305
Cyclopentane, vinyl-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 281
Cyclopentane, 2-vinyl-1-methylene-
  synthesis
    *via* intramolecular ene reaction, 15
Cyclopentaneacetic acid, vinyl-
  synthesis
    *via* palladium-ene reactions, 55
Cyclopentanecarboxylic acid
  esters
    synthesis *via* [3 + 2] cycloaddition reactions, 282
Cyclopentanecarboxylic acid, 3-methylene-
  esters
    synthesis *via* metal-catalyzed codimerization, 1191
1,2-Cyclopentanediol, *cis*-4-methylene-
  synthesis, 246
Cyclopentanes
  annulation
    *via* free radical reaction, 926
  synthesis
    *via* ene reactions, 9
    *via* intramolecular ene reactions, 21

1*H*-Cyclopenta[*c*]pyrroles
  synthesis
    *via* metal-catalyzed cycloaddition, 1194
1*H*-Cyclopenta[*c*]pyrrolo-1,3-diones, 5-alkylidenehexahydro-
  synthesis
    *via* metal-catalyzed cycloaddition, 1194
Cyclopentene, 1-acetoxy-
  Pauson–Khand reaction, 1048
Cyclopentene, 1,2-dimethoxy-
  synthesis, 1083
Cyclopentene, methoxy-
  cycloaddition reactions
    with benzonitrile, 161
Cyclopentene, 1-methyl-
  cyclopropanation, 1085
  Pauson–Khand reaction, 1046
Cyclopentene, 3-methylene-
  annulation, 774
2-Cyclopentene, 1-methylimino-3-methyl-5,5-diphenyl-
  synthesis
    *via* metal-catalyzed cycloaddition, 1195
Cyclopentene, vinyl-
  synthesis
    nickel-catalyzed rearrangement, 917
Cyclopentene-1,2-diones
  synthesis
    *via* metal-catalyzed cycloaddition, 1200
4-Cyclopentene-1,3-diones, 2-alkylidene-
  synthesis
    *via* cyclobutenone ring opening, 690
Cyclopentenes
  annulation, 951
    opening of cyclopropyl ketones, 925
    use of vinylcyclopropane, 919
  [2 + 2 + 2] cycloaddition reactions, 1130
  irradiation
    with *m*-xylene, 651
  Pauson–Khand reaction, 1046
  rearrangement
    vinylcyclopropane, 907
  synthesis
    selectivity, 907
    *via* [4 + 1] annulation, 1008
    *via* [3 + 2] cycloaddition reactions, 277
    *via* vinylcyclopropane rearrangement, 1012
Cyclopentenes, 3-(3-butynyl)-
  Pauson–Khand reaction, 1057, 1058
Cyclopentenes, 4-methylene-
  synthesis
    *via* metal-catalyzed cycloaddition, 1194
    *via* retro Diels–Alder reactions, 563
Cyclopentenes, 1-(4-pentynyl)-
  Pauson–Khand reaction, 1057, 1062
Cyclopentenes, 3-substituted 1-vinyl-
  Diels–Alder reactions, 349
Cyclopentenols
  synthesis
    *via* retro Diels–Alder reactions, 562

2-Cyclopentenone, 3-alkylidene-
  synthesis
    *via* Nazarov cyclization, 777
Cyclopentenone, 3-*n*-butyl-
  photocycloaddition reactions, 125, 127
2-Cyclopentenone, 5-chloro-
  synthesis
    *via* Nazarov cyclization, 777
2-Cyclopentenone, 2,5-dimethyl-
  synthesis
    *via* vinylallene epoxidation, 772
Cyclopentenone, 2-ethoxycarbonyl-
  [3 + 2] cycloaddition reactions, 273
2-Cyclopentenone, 3-phenylthio-
  synthesis
    *via* Nazarov cyclization, 778
2-Cyclopentenone, 5-phenylthio-
  synthesis
    *via* Nazarov cyclization, 778
Cyclopentenones
  [3 + 2] cycloaddition reactions
    palladium catalyzed, 281
  functionalized
    synthesis *via* retro Diels–Alder reactions, 560
  isomerization, 762
  photocycloaddition reactions
    stereochemical scrambling, 128
  synthesis, 1105
    *via* [2 + 2 + 2] cycloaddition, 1131–1133
    *via* [3 + 2] cycloaddition reactions, 283–286
    *via* Nazarov cyclization, 757
    *via* Pauson–Khand reaction, 1037
    *via* vinylallene epoxidation, 772
2-Cyclopentenones
  [3 + 2] cycloaddition reactions, 301
  synthesis
    *via* hydration of dienynes/ring closure, 752
Cyclopentenones, 3-alkyl-4-(hydroxyalkyl)-
  synthesis
    *via* Pauson–Khand reaction, 1057
Cyclopentenones, 5-aryl-
  synthesis
    *via* Pauson–Khand reaction, 1045
Cyclopentenones, α,α′-dialkyl-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 285
Cyclopentenones, 4,4-disubstituted 3-methyl-
  synthesis
    *via* Nazarov cyclization, 767
2-Cyclopentenones, 4-hydroxy-
  synthesis
    *via* Nazarov cyclization, 771
2-Cyclopentenones, 4-methyl-
  synthesis
    *via* Nazarov cyclization, 767
Cyclopentenones, 4-methylene-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1131
Cyclopentenones, 5-methylene-
  synthesis
    *via* Nazarov cyclization, 780
    *via* retro Diels–Alder reactions, 560

6,7,8,9-Dibenzobicyclo[3.2.2]nonan-3-one
  synthesis
    *via* [4 + 3] cycloaddition, 608
Dibenzo[*a*,*e*]cyclooctadiene, 5,6,11,12-tetrahydro-
  synthesis
    *via* [4 + 4] cycloaddition, 639
Dibenzofurans
  photochemical ring opening, 712
Dibenzofurans, hydroxy-
  synthesis
    *via* FVP, 732
Dibenzo systems
  photoisomerization, 197
1,4-Dicarbonyl compounds
  synthesis, 941
    use of cyclopropanes, 903
1,3-Dicarbonyl compounds, alkylidene-
  Diels–Alder reactions, 467
1,3-Dicarbonyl compounds, arylidene-
  Diels–Alder reactions, 467
Dichlorides
  geminal
    solvolysis, divinyl ketones from, 770
Dictyopterene C′
  synthesis
    *via* Cope rearrangement, 973
Dictyopterene
  synthesis
    *via* Cope rearrangement, 803
Dicyclopenta[*a*,*d*]cyclooctanes
  synthesis
    *via* divinylcyclobutane rearrangement, 1029
Dicyclopentadiene
  reaction injection molding, 1120
  ring opening metathesis polymerization, 1120
Dicyclopropylimine
  rearrangement, 945
Dideuteriomethylenation
  modified Tebbe reagent, 1125
Diels–Alder reactions
  activation enthalpy, 317
  activation entropy, 317
  benzannulation
    tandem, 1099
  benzynes
    regiochemistry, 390–393
    stereochemistry, 390–393
  cationic heterodienes, 492–507
  chiral catalysts, 376–379
  clays as promoters, 345
  diastereoface selective, 347–352

  diastereoselectivity
    conformational effects, 526
    relative, 514, 532–543
    simple, 514, 515–532
  endocyclic dienophiles, 371
  π-facial control, 319
  heterodienes, 451–507
  heterodienophiles, 320–328, 402–444
  high pressure promoted, 341–343
  imines
    intramolecular, 413–416
  intermolecular, 315–396
    reactivity, 316
  intramolecular, 513–546
    asymmetric, 543–546
    carbonyl compounds, 435
    diastereoselectivity, 522–526
    Lewis acid catalyzed, 519–522
  inverse electron demand, 452
  Lewis acid promoted, 339–346
  mechanism, 451
  medium promoted, 339–346
  neutral, 452
  normal, 452
  regiochemistry, 317
  retrograde, 551–589
    intramolecular, 584–587
  silica gel as promoter, 345
  stereochemistry, 318
  stereoface selective, 352–379
  tandem ene reactions
    alkynes, 7
  transannular cycloadditions, 532
  ultrasound promoted, 341–343
  volume of activation, 458
  water promoted, 344
  zeolites as promoters, 345
Dienamides
  Diels–Alder reactions, 331
Dienamines
  acrylic
    Diels–Alder reactions, 331
Dienes
  bicyclization, 1172
  boron-substituted
    Diels–Alder reactions, 335–337
  chiral
    Diels–Alder reactions, 348–350, 373–376
  conjugated
    [3 + 2] cycloaddition reactions, 297
    reaction with chlorosulfonyl isocyanate, 105
  conjugated acyclic
    Pauson–Khand reaction, 1044
  cyclic
    photoisomerizations, 196
  cycloaddition reactions
    fulvenes, 626–630
    tropones, 618–625
  [3 + 2] cycloaddition reactions, 307
  [4 + 3] cycloaddition reactions, 601
  heteroatom-substituted
    Diels–Alder reactions, 328–339
  heterodienophile additions, 401–444
  nitrogen-substituted
    Diels–Alder reactions, 331–333
  oxygen-substituted
    Diels–Alder reactions, 329–331, 434
  polycyclic
    photoisomerization, 196
  silicon-substituted
    Diels–Alder reactions, 335–337
  sulfur-substituted
    Diels–Alder reactions, 333
  tin-substituted
    Diels–Alder reactions, 335–337
  unactivated
    photocycloaddition reactions, 145
1,3-Dienes
  coupling with carbene complexes, 1084
  cyclic
    [4 + 3] cycloaddition reactions, 603–605
  cycloaddition reactions with alkynyl carbene complexes, 1072
  insertion reactions
    allylpalladium compounds, 35
  open-chain
    [4 + 3] cycloaddition reactions, 603
  photocycloaddition reactions, 635–638
  reactions with iron carbene complexes, 1088
  synthesis
    *via* cyclobutenes, 683–686, 1030
    *via* Pauson–Khand reaction, 1039, 1043
1,4-Dienes
  acyclic
    photoisomerizations, 195
  photoisomerization, 194–213
    *cis–trans*, 207
  retro-ene reaction, 907
  synthesis
    *via* boron-ene reaction, 34
    *via* palladium-ene reactions, 56
1,5-Dienes
  synthesis
    *via* palladium-ene reaction, 48
  thermal rearrangement, 786
1,6-Dienes
  ene reactions, 10–15
1,7-Dienes
  ene reactions
    intramolecular, 17
α,ω-Dienes
  cycloaddition with nickel(0) complexes, 1131
  synthesis
    alkene metathesis, 1117
Dienes, acetoxy-
  palladium-ene reactions, 46
1,5-Dienes, 1-acyl-
  Cope rearrangement
    catalysis, 799
1,5-Dienes, 2-acyl-
  Cope rearrangement
    catalysis, 798
1,5-Dienes, 3-acyl-
  Cope rearrangement
    catalysis, 799
Dienes, *N*-acylamino-
  Diels–Alder reactions, 331
Dienes, 2-alkoxy-
  Diels–Alder reactions, 348
1,3-Dienes, 1-amino-
  Diels–Alder reactions, 331
1,3-Dienes, 2-dialkylamino-

  Diels–Alder reactions, 331
1,4-Dienes, 2-ethoxy-
  synthesis
    *via* boron-ene reaction, 34
Dienes, 1-(*O*-methylmandeloxy)-
  Diels–Alder reactions, 373
1,3-Dienes, 2-(phenylsulfonyl)-
  Diels–Alder reactions, 333
Dienes, siloxy-
  Diels–Alder reactions, 329, 407
1,3-Dienes, 2-(silylmethyl)-
  Diels–Alder reactions, 337–339
1,3-Dienes, 2-(stannylmethyl)-
  Diels–Alder reactions, 337–339
1,3-Dienes, 2-(thiomethyl)-
  Diels–Alder reactions, 337–339
Dienoates
  synthesis
    *via* nickel-ene reaction, 36
*o*-Dienones
  synthesis
    *via* Claisen rearrangement, 834
Dienophiles
  chiral
    Diels–Alder reactions, 350–352, 354–373
  Diels–Alder reactions
    intramolecular, 531
Dienyl systems
  Paterno–Büchi reaction, 165–168
Dienynes
  divinyl ketones from
    cyclization, 767
  hydration, 752
1,11-Dien-6-ynes
  intramolecular [2 + 2 + 2] cycloaddition, 1141
1,13-Dien-7-ynes
  intramolecular [2 + 2 + 2] cycloaddition, 1141
Diimides, alkoxycarbonylaroyl-
  Diels–Alder reactions, 486
Diimides, arylaroyl-
  Diels–Alder reactions, 486
Diimides, diaroyl-
  Diels–Alder reactions, 486
ε-Diketones
  β,γ-unsaturated
    photoisomerizations, 227
Di-π-methane rearrangements
  chemoselectivity, 206
  hetero-substituted, 199–202
  lamps and filters, 212
  mechanism, 202–206
    benzo–vinyl bridging, 203
    divinyl bridging, 203
  nomenclature, 194
  photochemical apparatus, 212
  photochemical hazards, 213
  photochemical reaction conditions, 212
  photoisomerizations, 193–213
  practical aspects, 212
  regioselectivity, 209
  scope, 195–202
  selectivity, 206–211
  stereoselectivity, 210
  synthetic utility, 211
Dimethyl fumarate
  Diels–Alder reactions
    Lewis acid promoted, 339
Dimethyl itaconate
  ene reactions
    Lewis acid catalysis, 5
Dimethyl maleate
  [3 + 2] cycloaddition reactions, 300
  Diels–Alder reactions, 392
Dimethyl muconate
  [3 + 2] cycloaddition reactions, 297, 307
Diosphenol
  synthesis
    *via* Claisen rearrangement, 848
2,7-Dioxabicyclo[3.2.0]hept-3-ene
  photocycloaddition reactions, 170
  synthesis
    *via* photocycloaddition, 168
2,7-Dioxabicyclo[3.2.0]hept-3-ene-6-carboxylic acid
  menthyl ester
    synthesis *via* photocycloaddition, 169
3,7-Dioxabicyclo[3.3.0]oct-1(5)-ene
  synthesis
    *via* retro Diels–Alder reactions, 579
Dioxaspiro[3,3]heptanes
  synthesis
    *via* photocycloaddition, 167
1,2-Dioxetanes
  excited states
    thermal generation, 198
1,3-Dioxole, 2,2-diisopropyl-
  cycloaddition reactions
    ethyl pyruvate, 160
1,3-Dioxole, 2,2-dimethyl-
  photocycloaddition reaction
    methyl phenyl glyoxylate, 160
Dioxolenium ions
  Diels–Alder reactions
    intramolecular, 519
Dioxolenones
  photocycloaddition reactions, 134, 137
1,3-Dioxoles
  photolysis, 154
Dioxygen trapping
  Paterno–Büchi reaction, 155
Dipeptides
  hydroxyethylene isosteres
    synthesis *via* Carroll rearrangement, 836
  *N*-methylation
    retrograde Diels–Alder reaction, 552
1,3-Dipolar cycloaddition reactions, 247
  absolute stereoselection, 260
  regioselectivity, 247
  relative stereoselection, 254
  stereoselectivity, 254
  synthetic equivalents, 266
1,3-Dipoles
  cycloaddition reactions
    fulvenes, 630
    tropones, 625
Dipropargylamines
  intramolecular cycloaddition reactions, 1154
Dipyridones
  photodimerization, 638
Diquinane enone
  photocycloaddition reactions, 144
Diquinanes
  synthesis

    *via* intramolecular ene reaction, 11
    *via* photoisomerizations, 226
    *via* rhodium-catalyzed rearrangement, 916
*o*-Diquinomethanes
  Diels–Alder reactions, 524
7,8-Disilabicyclo[2.2.2]octa-2,5-dienes
  thermolysis
    *via* retro Diels–Alder reaction, 587
Disilenes
  generation
    *via* retro Diels–Alder reaction, 587
Diterpene alkaloids
  synthesis
    *via* benzocyclobutene ring opening, 693
4*H*-1,3-Dithiins
  synthesis
    *via* dimerization of thioketones, 556
Dithioesters
  Diels–Alder reactions, 438
Dithioformic acid, cyano-
  methyl ester
    Diels–Alder reactions, 439
1,3-Diyl trapping reaction
  intermolecular
    trimethylenemethane, 240
  intramolecular
    trimethylenemethane, 241
  trimethylenemethane, 239
Diynes
  bicyclization, 1171
    zirconium-promoted, 1164
  intramolecular cycloaddition reactions
    bicyclic 2-pyrone synthesis, 1157
1,5-Diynes
  Cope rearrangement, 797
α,ω-Diynes
  cycloaddition reactions
    isocyanates, 1156
  intramolecular cycloaddition reactions
    nitriles, 1154
9,11-Dodecadien-1-ol
  acetate
    synthesis *via* retro Diels–Alder reaction, 567
Dodecahedranes
  synthesis
    *via* Diels–Alder reaction, 347
    *via* Nazarov cyclization, 768
    *via* Pauson–Khand reaction, 1062
Drimanes
  synthesis
    *via* Diels–Alder reaction, 331
Drimatriene sulfoxide
  synthesis
    *via* electrocyclization, 735
Dynemicin A
  synthesis
    *via* electrocyclization, 736

Ebelactone A
  synthesis
    *via* Ireland rearrangement, 842
Eight-membered carbocycles
  synthesis
    *via* [4 + 4] cycloaddition, 635
Elaeokanine A
  synthesis
    *via* retro Diels–Alder reaction, 567
Electrocyclic processes
  higher order, 743
Electrocyclization
  1,3,5-hexatrienes, 706–730
  orbital correlation diagram, 703
  six-electron
    1,3,5-hexatriene, 699
  stereochemistry, 703–706
Ellipticine
  synthesis
    *via* Diels–Alder reaction, 384
    *via* electrocyclization, 721
Enamides
  Diels–Alder reactions, 322–324
Enamines
  [2 + 2] cycloaddition reactions, 71
  [3 + 2] cycloaddition reactions
    iron catalyzed, 285
  Diels–Alder reactions, 322–324
  reactions with isocyanates, 103
  synthesis
    *via* amide methylenation using Tebbe reagent, 1124
    *via* retro Diels–Alder reactions, 558
Enamines, α-chloro-
  cyclic
    generation of 2-aminoallyl cations, 597
  [4 + 3] cycloaddition reactions, 608
  synthesis, 109
Enamines, tetramethyl-α-chloro-
  β-lactams from, 112
Endiandric acids
  synthesis
    *via* electrocyclization, 743
Enediols
  synthesis
    *via* retro Diels–Alder reactions, 557
1-Ene-6,12-diynes
  intramolecular cycloadditions, 1144
7-Ene-1,13-diynes
  intramolecular cycloadditions, 1144
Ene reactions
  alkenes
    enophiles, 1–25
    Lewis acid catalysis, 4–6
  alkynes
    Lewis acid catalysis, 7–9
  carbene complexes, 1075
  enantioselective, 13
  intermolecular, 2–9
  intramolecular
    alkenes, 9–20
    enols, 20–23
  Lewis acid catalysis, 1
  tandem Claisen rearrangement, 11
  tandem Diels–Alder reaction
    alkynes, 7
  thermal
    alkenes, 2–4
    alkynes, 6
    *cis/trans* selectivity, 3
    *endo/exo* selectivity, 3
    regioselectivity, 3
  transannular, 20
Enoates
  Diels–Alder reactions, 354–359

Enolates
  2-acetidinone synthesis, 100–102
Enol ethers
  2-acetidinone synthesis, 100–102
  cyclic
    photoreactions with benzonitrile, 161
  cycloaddition reactions
    alkynic carbene complexes, 1067
  ene reactions, 1075
  synthesis
    *via* esters using Tebbe methylenation reagent, 1123
Enol ethers, alkyl-
  ene reactions, 1075
Enol ethers, silyl-
  ene reactions, 1075
Enol lactones
  synthesis
    *via* retro Diels–Alder reactions, 561
Enols
  ene reactions
    intramolecular, 20–23
  synthesis
    *via* retro Diels–Alder reactions, 557
β,γ-Enones
  bridged
    photoisomerizations, 224–228
  bridged bicyclic
    photoisomerizations, 228
  photoisomerizations, 215
Enones, β′-amino-
  divinyl ketones from
    cyclization, 766
Enones, β′-chloro-
  divinyl ketones from
    cyclization, 766
Enones, α′-hydroxy-
  divinyl ketones from
    cyclization, 766
Enones, β′-substituted
  divinyl ketones from
    cyclization, 766
Enones, β-(2-vinylcyclopropyl)-
  synthesis, 979
Enynes
  acyclic
    Pauson–Khand reaction, 1053–1055
  acyclic heteroatom-containing
    Pauson–Khand reaction, 1055
  bicyclization, 1165–1170
    zirconium-promoted, 1163–1183
  bicyclization–carbonylation, 1165
  cyclic
    Pauson–Khand reaction, 1057–1060
  intramolecular cycloaddition with isocyanides, 1132
  reaction with Fischer carbene complexes, 1104
  synthesis
    *via* Sakurai–Hosomi allylsilane conjugate addition, 1166
1,4-Enynes
  synthesis
    *via* boron-ene reaction, 34
1,5-Enynes
  Cope rearrangement, 797
1,6-Enynes
  cyclization *via* intramolecular ene reaction
    palladium catalysis, 16
  ene reactions
    intramolecular, 15–17
1,7-Enynes
  ene reactions
    intramolecular, 18
α,ω-Enynes
  intramolecular cycloaddition reactions, 1143
Enynols
  divinyl ketones from
    cyclization, 768
Ephedrine
  Diels–Alder reactions
    intramolecular, 545
Epicampherenone
  synthesis
    *via* [3 + 2] cycloaddition reactions, 286
14-Epicorynoline
  synthesis
    *via* Diels–Alder reaction, 500
Epiepoformine
  synthesis
    *via* retro Diels–Alder reactions, 564
Epiepoxydon
  synthesis
    *via* retro Diels–Alder reactions, 564
Epimodhephene
  synthesis
    *via* intramolecular ene reactions, 22
Epipentenomycin
  synthesis
    *via* retro Diels–Alder reactions, 561
Epiprecapnelladiene
  synthesis
    *via* photocycloaddition, 139
4-Epishikimic acid
  synthesis
    *via* Diels–Alder reaction, 373
Epoformine
  synthesis
    *via* retro Diels–Alder reactions, 564
Epoxydon
  synthesis
    *via* retro Diels–Alder reactions, 564
Equisetin
  synthesis
    *via* Ireland rearrangement, 843
Erigerol
  synthesis
    *via* Diels–Alder reaction, 329
Erythrina alkaloids
  synthesis
    *via* Diels–Alder reactions, 323
Eschenmoser amide acetal rearrangement
  variant of Claisen rearrangement, 836–838
Esperamicin
  synthesis
    *via* electrocyclization, 736
Esters
  acyclic
    synthesis *via* retro Diels–Alder reactions, 573
  alkenic
    divinyl ketones from, 776
  alkylidenation
    dihaloalkane reagents, 1125
  methylenation
    Tebbe reagent, 1123

  α,β-unsaturated
    synthesis *via* retro Diels–Alder reaction, 553
Esters, β-keto-2-[2-(trimethylsilyl)methyl]-
  cycloaddition reactions, 247
Esters, α-keto-β,γ-unsaturated
  Diels–Alder reactions, 461
Esters, α,β-unsaturated
  chelated
    Diels–Alder reactions, 365–367
  Diels–Alder reactions, 461
Esters, vinyl
  cycloaddition reactions, 255
Estradiol
  synthesis
    *via* benzocyclobutene ring opening, 693
Estrone
  synthesis
    *via* benzocyclobutene ring opening, 693
    *via* Cope rearrangement, 790
Estrone, C,18-bisnor-13α,17α-dehydro-
  synthesis
    *via* photoisomerization, 232
9,10-Ethanoanthracene, 9,10-dihydro-
  retro Diels–Alder reaction, 589
Ether, *n*-butyl vinyl
  reaction with tetracyanoethylene
    thermochemistry, 76
Ether, ethyl propenyl
  [2 + 2] cycloaddition reactions, 1067
Ether, methyl tropyl
  synthesis
    *via* 1,3-sigmatropic shift, 1003
Ether, *trans*-propenyl ethyl
  reaction with tetracyanoethylene, 78
Ether, propenyl methyl
  [2 + 2] cycloaddition reactions, 75
Ethers, alkyl vinyl
  reaction with tetracyanoethylene
    solvent effects, 76
Ethers, allyl
  cycloaddition reactions, 260
  inside alkoxy effect
    cycloaddition reactions, 260
  Pauson–Khand reaction
    regiocontrol, 1044
Ethers, allyl propargyl
  Pauson–Khand reaction, 1055
Ethers, allyl vinyl
  Claisen rearrangement, 832–834, 1001
    discovery, 827
  synthesis
    *via* Claisen rearrangement, 830–832
    *via* Wittig-type alkenation, 830
Ethers, bisallyl vinyl
  Claisen rearrangement
    catalysis, 850
Ethers, crotyl propargyl
  ene reactions
    intramolecular, 16
Ethers, crotyl propenyl
  Claisen rearrangement
    transition state structures, 857
Ethers, dipropargyl
  intramolecular cycloaddition reactions
    pyridoxine synthesis, 1154
Ethers, divinyl
  photoisomerization, 200
Ethers, ethyl vinyl
  cycloaddition reactions
    propynyl tungsten complexes, 1073
Ethers, $\eta^1$-iron allyl vinyl
  Claisen rearrangement, 1075
Ethers, methyl cyclohexenyl
  ene reactions, 1075
Ethers, neopentyl
  Diels–Alder reactions, 356
Ethers, vinyl
  cycloaddition reactions, 255
  [2 + 2] cycloaddition reactions, 73
  Diels–Alder reactions, 372
  Pauson–Khand reaction, 1045
  reaction with ketene acetals, 684
Ethylenamine
  synthesis
    *via* retro Diels–Alder reactions, 558
Ethylene
  Pauson–Khand reaction, 1043
Ethylene, alkoxy-
  reaction with tetracyanoethylene, 71
Ethylene, 1,2-bis(trifluoromethyl)-1,2-dicyano-
  [2 + 2] cycloaddition reactions, 75
  reaction with tetramethoxyethylene, 75
Ethylene, 1-cyano-1-alkoxycarbonyl-
  [2 + 2] cycloaddition reactions, 73
Ethylene, cyclopropyl-
  photoaddition reactions
    aromatic carbonyl compounds, 165
Ethylene, 1,1-dichloro-2,2-difluoro-
  addition reactions with conjugated dienes, 69
Ethylene, 1,1-dicyano-
  [2 + 2] cycloaddition reactions
    hydroxyethylene, 72
Ethylene, 1,1-difluoro-
  reaction with butadiene, 70
Ethylene, 1,1-difluoro-2,2-dichloro-
  intramolecular [2 + 2] cycloadditions, 69
  reaction with butadiene, 71
Ethylene, hydroxy-
  [2 + 2] cycloaddition reactions, 72
Ethylene, nitro-
  Diels–Alder reactions, 320
  ene reactions
    thermal, 3
Ethylene, 1-nitro-2-(3,4-methylenedioxyphenyl)-
  reaction with azomethine ylides, 265
Ethylene, β-sulfinylnitro-
  Diels–Alder reactions, 320
Ethylene, tetracyano-
  adduct with 7-methylenenorbornadiene, 65
  cycloaddition reactions, 273
    alkenes, 71
  [2 + 2] cycloaddition reactions
    hydroxyethylene, 72
    propenylidenecyclopropane, 76
  Diels–Alder reaction
    9,10-dimethylanthracene, 76
  ene reactions
    intermolecular, 3
  polymerization initiation, 74
  reaction with anthracene
    thermochemistry, 76
  reaction with *p*-methoxystyrene

    - solvent effects, 75
- Ethylene, tetrafluoro-
  - cycloaddition reactions, 70
  - intramolecular [2 + 2] cycloadditions, 69
- Ethylene, tetramethoxy-
  - reaction with 1,2-bis(trifluoromethyl)-1,2-dicyanoethylene, 75
- Ethylene, tetramethyl-
  - photolysis
    - with 3-pentyn-2-one, 164
- Ethylene, tetravinyl-
  - synthesis
    - *via* photolysis, 738
- Ethylene, trifluoro-
  - reaction with butadiene, 70
- Ethylenediamine, *N,N'*-benzylidene-
  - [4 + 3] cycloaddition reactions, 598
- Ethylene-1,2-diols
  - synthesis
    - *via* retro Diels–Alder reactions, 557
- Ethylenetricarboxylates, 1-allylic 2,2-dimethyl
  - cyclization
    - intramolecular ene reaction, 12
  - Diels–Alder reactions, 461
- Ethyl 3-furoate
  - [4 + 3] cycloaddition with 1-phenyl-2-oxyallyl, 601
- Ethyl oleate
  - metathesis
    - tungsten catalysts, 1118
- Ethyl propiolate
  - Diels–Alder reactions, 320
- Eucannabinolide
  - synthesis
    - *via* Cope rearrangement, 809

- Fabianine
  - synthesis
    - *via* Diels–Alder reaction, 492
- Fastigilin-C
  - synthesis
    - *via* Claisen rearrangement, 851
- Fatty acid alcohols
  - synthesis
    - alkene metathesis, 1117
- Fenestranes
  - synthesis
    - *via* photocycloaddition reactions, 136
- Ferrier-type rearrangements
  - Claisen rearrangements
    - competition, 850
- Fischer carbene complexes
  - reactions with alkynes
    - alkyne concentration, 1099
    - mechanisms, 1094
    - solvents, 1099
- FK-506
  - synthesis
    - *via* Ireland rearrangement, 843
- Flash vapor pyrolysis
  - retrograde Diels–Alder reactions, 552
- Flavenes
  - synthesis
    - *via* aromatic Claisen rearrangement, 834
- Fluorene, 9-(difluoromethylene)-
  - cycloaddition reactions, 70
- Formaldehyde
  - Diels–Alder reactions, 433
- Formamide, *N,N*-dimethyl-
  - dialkyl acetals
    - reaction with carbene complexes, 1079
- Formate, cyano-
  - Diels–Alder reactions, 416
- Formonitrile, (ethoxycarbonyl)-
  - oxide
    - reaction with isopropylidene-3-butene-1,2-diol, 262
- Forskolin
  - synthesis
    - *via* Cope rearrangement, 814
- Forsythide
  - aglucone dimethyl ester
    - synthesis *via* photoisomerization, 231
- Frenolicin, deoxy-
  - synthesis, 1096
    - *via* cyclobutenone ring opening, 690
    - regioselective, 1094
- Fulgides
  - photochemical ring closure, 722
- Fulvene, 6-amino-
  - cycloaddition reactions
    - α-pyrones, 626
- Fulvene, 6,6-dialkyl-
  - [4 + 3] cycloaddition reactions, 604
- Fulvene, 9,10-dihydro-
  - Diels–Alder reactions, 347
- Fulvene, 6,6-dimethyl-
  - cycloaddition reactions
    - benzocyclobutenes, 627
    - dienes, 626
    - nitropyridyl betaines, 630
    - tropones, 631
  - retro Diels–Alder reaction, 563
- Fulvene, 6-(dimethylamino)-
  - cycloaddition reactions
    - dienes, 627
    - thiophenes, 629
  - [4 + 3] cycloaddition reactions, 604
- Fulvene, 6,6-diphenyl-
  - cycloaddition reactions
    - dienes, 627
- Fulvene, 6-methyl-
  - cycloaddition reactions
    - dienes, 629
- Fulvenes
  - anthracene adduct
    - retro Diels–Alder reaction, 589
  - cycloaddition reactions, 626
  - [4 + 3] cycloaddition reactions, 604
  - Pauson–Khand reaction, 1046
  - retrograde Diels–Alder reactions, 552
  - synthesis
    - *via* benzene irradiation, 646
- Fumarates, dimenthyl-
  - Diels–Alder reactions, 355
- Fumaric acid, cyano-
  - dimethyl ester
    - [2 + 2] cycloaddition reactions, 73
- Furan, alkylidenetetrahydro-
  - synthesis
    - *via* [3 + 2] cycloaddition reactions, 283
- Furan, 2,5-dihydro-3,4-dimethyl-
  - synthesis
    - *via* retro Diels–Alder reactions, 579

Furan, 2,3-dihydro-2,3-dimethylene-
  synthesis
    *via* retro Diels–Alder reactions, 579
Furan, 2,3-dimethylene-
  dimerization, 638
    *via* [4 + 4] cycloaddition, 639
Furan, 2-methoxycarbonyl-
  Diels–Alder reactions, 382
Furan, 2-methyl-
  [4 + 3] cycloaddition reactions, 606
Furan, 3-methyl-
  [4 + 3] cycloaddition with 1-phenyl-2-oxyallyl, 601
Furan, 3-methylenetetrahydro-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 307
    *via* metal-catalyzed cycloaddition, 1196
Furan, tetramethylenetetrahydro-
  synthesis
    *via* retro Diels–Alder reactions, 579
Furandiones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1138
Furanether B
  synthesis
    *via* Pauson–Khand reaction, 1052
3-Furanmethanol
  synthesis
    *via* photocycloaddition, 169
Furanones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1136–1138
    *via* [3 + 2] cycloaddition reactions, 286
Furanones, tetrahydro-
  synthesis, 943
Furanoterpenes
  synthesis
    *via* retro Diels–Alder reactions, 579
Furans
  [4 + 3] cycloaddition reactions, 605–607
  Diels–Alder reactions, 342, 380–383
    comparison of promoters, 345
  photocycloaddition reactions
    benzene, 637
    carbonyl compounds, 168–178
  retrograde Diels–Alder reactions, 552
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1092, 1136
    *via* Diels–Alder reactions, 491
Furans, dihydro-
  [2 + 3] annulation, 930
  Pauson–Khand reaction, 1046
  synthesis
    selectivity, 907
    *via* [3 + 2] cycloaddition reactions, 279
    *via* metal-catalyzed cycloaddition, 1200
    *via* [2 + 3] reaction, 951
    *via* rearrangements, 952
    *via* retro Diels–Alder reactions, 579
    *via* vinyloxiranes, 929
Furans, tetrahydro-
  synthesis
    *via* metal-catalyzed cycloaddition, 1200
    *via* palladium-ene reactions, 51
    *via* vinyloxiranes, 927
2-Furfuryl alcohol
  Claisen–Cope rearrangement, 879
Furfurylidene carbinols
  electrocyclization, 771
Furo[3,4-*c*]pyridine
  synthesis
    *via* retro Diels–Alder reactions, 584
2-Furylcarbinols
  solvolysis
    divinyl ketones from, 771
3-Furylmethyl benzoate, 2-methyl-
  flash vacuum pyrolysis
    [4 + 4] cycloaddition, 639

Galactopyranose, cyclohexylidene-
  Paterno–Büchi photocycloaddition reaction
    with furan, 187
Geneserine
  synthesis
    *via* benzocyclobutene ring opening, 681
Geodiamolide A
  synthesis
    *via* Johnson rearrangement, 839
Gephyrotoxin 223AB
  synthesis
    *via* Diels–Alder reaction, 421
Germacrane
  synthesis
    *via* Cope rearrangement, 796
Germacranolides
  synthesis
    *via* Cope rearrangement, 809
Germacrone
  Cope rearrangement, 809
Germane, allyltrimethyl-
  ene reactions, 2
Gibberellin, 11-hydroxy-
  synthesis
    *via* intramolecular photocycloaddition, 180
Gibberellins
  methylenation
    modified Tebbe reagent, 1124
Ginkgolide B–kadsurenone hybrid
  synthesis
    *via* photocycloaddition, 176
Ginkolides
  synthesis
    *via* [3 + 2] cycloaddition reactions, 311
Glucals
  Paterno–Büchi reaction, 158
Glucofuranose
  Paterno–Büchi photocycloaddition reaction
    with furan, 187
α-Glucofuranose, 5-*O*,6-*O*-disilyl-3-*O*-acryloyl-1,2-*O*-isopropylidene-
    Diels–Alder reaction, 366
β-Glucopyranosides, 1,3-dienyltetraacetyl-
  Diels–Alder reactions, 374–376
Glucopyranosyl bromide, tetraacetyl-
  alkylation, 374
Glucopyranosyl radical
  synthesis
    *via* Paterno–Büchi reaction, 159
Glycals
  pyranoid
    Ireland–Claisen rearrangement, 859
  synthesis
    *via* isocyanate cycloaddition, 108

Glyceraldehyde acetonide
  imines
    condensation to β-lactams, 96
Glycinamide, *N*-phthaloyl-
  iminium salts from, 112
Glycinates, aroyl phenyl
  tandem rearrangements, 877
*C*-Glycosides
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
*C*-Glycosyl compounds
  synthesis
    *via* Paterno–Büchi reaction, 158
Glycoxylic acid, *p*-bromophenyl-
  menthyl ester
    crystal structure, 186
Glyoxalase inhibitor I
  synthesis
    *via* Diels–Alder reaction, 370
Glyoxylates
  *N*-acylimines
    Diels–Alder reactions, 405
Glyoxylic acid
  methyl ester
    Diels–Alder reactions, 431
  methyl phenyl ester
    photocycloaddition reactions, 160
Glyoxylic acid, phenyl-
  esters
    photocycloaddition reactions, 185
  2-(1-methyl-1-phenylethyl)-5-methylcyclohexyl ester
    crystal structure, 185
Gnididione
  synthesis
    *via* retro Diels–Alder reactions, 579
Grayanotoxins
  synthesis
    *via* photocycloaddition, 670
Griffin fragmentation
  photocycloreversion, 199
Grifolin
  synthesis
    *via* cyclobutenone ring opening, 689
    *via* electrocyclization, 732
Guaiane
  synthesis
    *via* photocycloaddition, 669
Guaianolides
  synthesis
    *via* Pauson–Khand reaction, 1052
Guaianolide sesquiterpenes
  synthesis
    *via* cycloaddition reactions, 275
Guaipyridine
  synthesis
    *via* Diels–Alder reaction, 492

Hafnabicycles
  synthesis, 1170
Hafnacycles
  three-membered
    synthesis, 1175
Hafnium catalysts
  bicyclization
    enynes, 1169
Hasubanan alkaloids
  synthesis
    *via* Diels–Alder reactions, 323
Hedycaryol
  Cope rearrangement, 809
Helianthrone
  photolysis, 729
Heliotridane, trihydroxy-
  synthesis, 940
Heliotridine
  synthesis
    *via* Diels–Alder reaction, 421
2,5-Heptadiene
  synthesis
    *via* retro Diels–Alder reaction, 567
Heptadiene, diphenyl-
  intramolecular [2 + 2] cycloadditions, 67
2,6-Heptadienoic acid
  synthesis
    *via* nickel-ene reaction, 36
4,6-Heptadienoic acid
  sodium salt
    Diels–Alder reactions, 344
1,6-Heptadiyne
  thermal isomerization, 736
Heptafulvene, 8,8-dimethyl-
  cycloaddition reactions
    dienes, 634
Heptahendecafulvadiene
  pericyclic reactions, 744
4-Heptanone, 3,5-dibromo-2,6-dimethyl-
  [4 + 3] cycloaddition reactions, 603
1,3,5-Heptatrienes
  thermal reactions, 707
Heptatrienones, amino-
  electrocyclization, 710
1-Heptene, 1-acetoxy-
  photocycloaddition reactions, 127
4-Heptenone, 2-hydroxy-
  synthesis
    *via* [4 + 3] cycloaddition, 603
1-Hepten-6-yne, 7-(trimethylsilyl)-
  bicyclization
    mechanism, 1178
  reaction with cyclopentadienylzirconium complexes, 1165
1-Hepten-6-ynes
  Pauson–Khand reaction, 1053
Heratomin
  synthesis, 1096
Hetero-Cope rearrangement
  carbanion-accelerated, 1004
Heterocyclic compounds
  four-membered
    synthesis, 85–118
  unsaturated
    synthesis *via* retro Diels–Alder reactions, 577–584
Heterodienes
  cationic
    Diels–Alder reactions, 492–507
  Diels–Alder reactions, 451–507
    intramolecular, 531
Heteroelectrocyclization
  applications, 740–743
Heterotropanone
  synthesis
    *via* retro Diels–Alder reaction, 569

Heteroyohimboid indole alkaloids
  synthesis
    *via* Diels–Alder reactions, 467
2,4-Hexadiene
  cycloaddition products, 69
  Diels–Alder reactions
    imines, 408
  isomerization, 74
1,5-Hexadiene, 3,4-dimethyl-
  Claisen rearrangement
    transition state structures, 857
  Cope rearrangement, 820
2,3-Hexadiene, 2,5-dimethyl-
  photocycloaddition reactions
    anthracene, 636
2,4-Hexadiene, 2,5-dimethyl-
  cycloaddition reactions, 71
  [2 + 2] cycloaddition reactions
    tetracyanoethylene, 76
  photocycloaddition reactions
    9-cyanoanthracene, 636
1,5-Hexadiene, 3,4-diphenyl-
  Cope rearrangement, 799
1,5-Hexadiene, 2-methyl-3-phenyl-
  Cope rearrangement
    palladium catalysts, 799
1,5-Hexadienes
  photocycloaddition reactions, 136
  reaction with chlorosulfonyl isocyanate, 105
  synthesis
    *via* Claisen–Cope rearrangement, 883
1,5-Hexadienes, 3-hydroxy-
  thermal rearrangements, 1000
2,4-Hexadienoic acid
  ethyl ester
    cycloaddition reactions, tropones, 620
3,5-Hexadienoic acid
  sodium salt
    Diels–Alder reactions, 344
3,5-Hexadienoic acid, 6-methoxy-
  sodium salt
    Diels–Alder reactions, 344
1,5-Hexadien-3-ol
  synthesis
    *via* 2,3-Wittig rearrangement, 888
1,5-Hexadiynes
  cooligomerization with alkynes
    benzocyclobutene synthesis, 692
Hexafuranos-5-ulose
  photocycloaddition reactions, 185
Hexalins
  photochemical ring opening, 739
  ring opening, 708
*trans*-$\Delta^{1,3}$-Hexalins
  photoisomerization, 706
Hexaquinacene
  synthesis
    *via* Nazarov cyclization, 768
Hexatrienes
  annulated
    electrocyclization, 711–730
  cyclic
    electrocyclization, 711–730
1,3,5-Hexatrienes
  electrocyclizations, 699, 706–730
  monoannulated
    electrocyclization, 711–721
Hexatrienes, amino-
  benzannulation, 720
  cyclization, 718
1,3,5-Hexatrienes, 1-dialkylamino-
  electrocyclization, 710
1-Hexene
  ene reactions
    Lewis acid catalysis, 4
2-Hexene, 2,5-dimethyl-4,5-epoxy-
  synthesis
    *via* photoisomerization, 201
2-Hexene, 6-phenyl-
  intramolecular cycloaddition, 649
  photocycloaddition reactions, 654, 658
3-Hexene-1,5-diyne, 1,6-dideuterio-
  thermal isomerization, 736
5-Hexenoic acid, 2-amino-4-methyl-
  synthesis
    *via* ene reaction of acrylate esters, 4
1-Hexen-5-ynes
  Pauson–Khand reaction, 1053
Hexofuranose
  photocycloaddition
    with furan, 170
1-Hexyne
  photolysis
    with benzaldehyde, 163
3-Hexyne
  cocycloaddition
    phenylacetylene, 1146
Hibiscone C
  synthesis
    *via* photocycloaddition, 145
β-Himachalene
  synthesis
    *via* Cope rearrangement, 803, 983
Hinokinin
  synthesis
    *via* retro Diels–Alder reactions, 578
Hinokitiol
  synthesis
    *via* [4 + 3] cycloaddition, 609
Hirsutene
  synthesis
    *via* [3 + 2] cycloaddition reactions, 310
    *via* Nazarov cyclization, 763, 779
    *via* photocycloaddition, 665, 666
Hirsutic acid
  synthesis
    *via* Pauson–Khand reaction, 1060
3-Homoadamantene
  dimerization, 65
Homoallylic alcohols
  1,3-sigmatropic rearrangements
    anion-accelerated, 1003
Homoallylic alcohols, dichloro-
  geminal
    solvolysis, divinyl ketones from, 771
Homobarrelene
  photoisomerization, 196
Homoestrone
  synthesis
    *via* benzocyclobutene ring opening, 693
4,5-Homotropones
  synthesis

    [4 + 3] cycloaddition reactions, 609
Hüchel molecular orbital calculations
  Claisen rearrangement, 856
Hydantoin, dehydro-
  Diels–Alder reactions, 406
  synthesis
    *via N*-chlorination, 406
Hydantoin, methoxy-
  Diels–Alder reactions, 406
Hydantoins, 5-ethoxy-
  synthesis, 1109
Hydrazones, α,β-unsaturated *N,N*-dimethyl-
  Diels–Alder reactions, 473
Hydrindane
  synthesis
    *via* retro Diels–Alder reaction, 572
Hydrindanone
  synthesis
    *via* cycloaddition reactions, 273
Hydrocarbons
  polyunsaturated substituted
    synthesis *via* retro Diels–Alder reaction, 565–573
Hydroxamic acids
  nitroso derivatives
    Diels–Alder reactions, 420

Ibogamine
  synthesis
    *via* Diels–Alder reaction, 373
Ikarugamycin
  synthesis
    *via* Cope rearrangement, 817
    *via* electrocyclization, 725
Imidazole, 2-(5-norbornen-2-yl)-
  synthesis
    *via* retro Diels–Alder reaction, 557
Imidazoles
  [2 + 2 + 2] cycloaddition reactions, 1143
  Diels–Alder reactions, 491
Imidazoles, 2-vinyl-
  synthesis
    *via* retro Diels–Alder reactions, 557
Imines
  2-acetidinone synthesis, 100–102
  aryl-substituted
    photoisomerization, 202
  2-azetidiniminium salts from, 108–113
  cyclic
    Diels–Alder reactions, 406–408
  cycloaddition reactions
    vinylidene complexes, 1068
  [3 + 2] cycloaddition reactions, 307
  Diels–Alder reactions, 402–416
  reactions with Fischer carbene complexes, 1107
  synthesis
    *via* aziridine thermolysis, 938
Imines, *C*-acyl-
  Diels–Alder reactions, 408
Imines, *N*-acyl-
  acyclic
    Diels–Alder reactions, 404
  Diels–Alder reactions, 404–408, 485
Imines, alkyl-
  Diels–Alder reactions, 409–411
Imines, aryl-
  Diels–Alder reactions, 409–411
Imines, cyclopropyl-
  rearrangements, 941
Imines, epoxy-
  synthesis
    *via* Sharpless epoxidation, 98
Imines, *N*-sulfonyl-
  Diels–Alder reactions, 402–404
Imines, thione
  Diels–Alder reactions, 441
Imines, α,β-unsaturated
  Diels–Alder reactions, 473
Imines, α,β-unsaturated *N*-phenylsulfonyl-
  Diels–Alder reactions, 473, 474
Iminium chloride, α-chloro-
  synthesis, 108
Iminium ions, *N*-acyl-
  [3 + 2] cycloaddition reactions
    with 1,3-dimethyl(*t*-butyldimethylsilyl)allene, 279
Immonium ions
  Diels–Alder reactions, 409–411, 492, 500
Immonium ions, *N*-alkylaryl-
  Diels–Alder reactions, 500
Indacrinone
  synthesis
    *via* Nazarov cyclization, 780
Indane
  intermolecular *meta* cycloaddition
    to vinyl acetate, 667
*trans*-Indane, 2-benzylidene-1-diphenylmethylene-
  photochemical reactions, 721
Indane, 1-phenyl-
  synthesis
    *via* photoisomerization, 208
1-Indanone
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1133
2-Indanone, perhydro-
  synthesis, 1173
Indanones
  angularly substituted
    synthesis *via* Nazarov cyclization, 760
*cis*-Indene, 8,9-dihydro-
  synthesis
    *via* thermal rearrangement, 716
*trans*-Indene, 8,9-dihydro-
  synthesis
    *via* photoisomerization, 716
Indene, hexahydro-
  *cis*-annulated
    synthesis *via* palladium-ene reaction, 50
Indene, 2-vinyl-
  synthesis
    *via* photoisomerization, 212
    *via* retro Diels–Alder reactions, 584
Indenes
  Pauson–Khand reaction, 1047
  synthesis
    *via* [3 + 2] cycloaddition reactions, 1090
    *via* photoisomerization, 197
Indenes, hydro-
  synthesis
    *via* Cope rearrangement, 812
Indenones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1135
Indoles

  [2 + 2 + 2] cycloaddition reactions, 1143
Indoles, dihydro-
  synthesis
    *via* electrocyclic ring closure, 713
Indoles, hydroxy-
  synthesis
    *via* FVP, 732
Indoles, 2-substituted
  synthesis
    *via* hetero-Cope rearrangement, 1004
Indoles, vinyl-
  thermolysis, 725
Indoline
  Cope rearrangement, 790
Indolones
  Diels–Alder reactions, 408
Ingenane diterpenoids
  synthesis
    *via* Cope rearrangement, 984
Ingenol
  synthesis
    *via* [6 + 4] cycloaddition, 624
    *via* Ireland rearrangement, 843
    *via* photocycloaddition reactions, 137
Inosamines
  synthesis
    *via* Diels–Alder reaction, 418
Insect pheromones
  synthesis
    *via* ene reaction, 8
    *via* photocycloaddition, 165
Invictolide
  synthesis
    using zirconium-promoted bicyclization of enynes, 1166
β-Ionone
  irradiation, 741
  synthesis
    *via* Carroll rearrangement, 835
Ionophores
  noncyclic
    synthesis *via* [4 + 3] cycloaddition, 612
Ipalbidine
  synthesis
    *via* Diels–Alder reaction, 411
Ipsenol
  synthesis
    *via* retro Diels–Alder reaction, 555
Iptycenes
  synthesis
    *via* Diels–Alder reaction, 383
Ireland silyl ester enolate rearrangement
  kinetics, 856
  variant of Claisen rearrangement, 840–847
Iridoids
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
Iridomyrmecin
  synthesis
    *via* magnesium-ene reaction, 41
    *via* photoisomerizations, 231
Iron, nonacarbonyldi-
  [3 + 2] cycloaddition reactions
    with α,α′-dibromo ketone, 282
Iron complexes
  α,β-unsaturated acyl
    Diels–Alder reaction, 367–369
Iron complexes, acryloyl-
  [3 + 2] cycloaddition reactions
    with allyltributyltin, 277
Iron complexes, allenyl-
  [3 + 2] cycloaddition reactions, 279
Iron complexes, $\eta^1$-allyl-
  [3 + 2] cycloaddition reactions, 272
    with toluenesulfonyl isocyanate, 275
Iron complexes, $\eta^1$-2-butenyl-
  [3 + 2] cycloaddition reactions, 273
Iron complexes, $\eta^1$-butynyl-
  [3 + 2] cycloaddition reactions
    with cyclohexenone, 277
Iron complexes, carbene
  reactions with alkenes, 1088
  reactions with 1,3-dienes, 1088
Iron complexes, cyclopentadienyl carbene
  cyclopropanation, 1086
Iron complexes, dicarbonyl-$\eta^5$-cyclopentadienyl-
  [3 + 2] cycloaddition reactions, 272
Iron complexes, $\eta^1$-2-methallyl-
  [3 + 2] cycloaddition reactions, 273
Iron complexes, 4-methyltroponetricarbonyl-
  [3 + 2] cycloaddition reactions, 274
Iron complexes, $\eta^1$-1-propynyl-
  [3 + 2] cycloaddition reactions
    with cyclohexenone, 280
Iron complexes, 2-propynyl-
  [3 + 2] cycloaddition reactions, 277
Iron complexes, α-thioalkyl-
  alkylation, 1086
Iron complexes, tricarbonyltropylium-
  [3 + 2] cycloaddition reactions, 274
  substituted
    [3 + 2] cycloaddition reactions, 274
Iron complexes, α,β-unsaturated acyl-
  [3 + 2] cycloaddition reactions
    with allylstannanes, 277
*cis*-γ-Irone
  precursor
    synthesis *via* intramolecular ene reaction, 18
Isobenzofuran
  Diels–Alder reactions, 413
  synthesis
    *via* Diels–Alder reactions, 382
    *via* retro Diels–Alder reactions, 580
Isobenzofuran, 1,3-diphenyl-
  Diels–Alder reactions
    selenoaldehydes, 442
Isoborneol, 10-mercapto-
  Michael addition, 370
Isoborneol-10-diisopropylsulfonamide
  esters
    reaction with imines, 102
Isobutene
  ene reactions
    Lewis acid catalysis, 4
  photolysis
    with 3-butyn-2-one, 164
Isobutyrophenone
  enolate
    Michael additions, 1082
Isocarbacyclin
  synthesis
    *via* Claisen rearrangement, 833

Isochroman-3-one
  synthesis
    *via* benzocyclobutene ring opening, 681
Isochromanones
  synthesis
    *via* hetero electrocyclization, 741
Isocomene
  synthesis
    *via* Carroll rearrangement, 835
    *via* intramolecular ene reaction, 11
    *via* Pauson–Khand reaction, 1062
    *via* photocycloaddition, 143, 660, 662
Isocyanates
  2-azetidinones from, 102–108
  cycloaddition reactions
    heterocycle synthesis, 1158
    with alkynes, 1155
Isocyanates, trichloroactelyl
  reaction with dihydropyrams
    glycal synthesis, 108
Isocyanides
  reactions with Fischer carbene complexes, 1109
Isodicyclopentadiene
  cycloaddition reactions
    tropones, 618
Isoellipticine
  synthesis
    *via* Diels–Alder reaction, 385
Isognididione
  synthesis
    *via* retro Diels–Alder reactions, 579
Isoheterotropanone
  synthesis
    *via* retro Diels–Alder reaction, 569
Isoindoles
  substituted
    synthesis *via* retro Diels–Alder reactions, 582
  synthesis
    *via* retro Diels–Alder reactions, 582
Isoingenol
  synthesis
    *via* [6 + 4] cycloaddition, 624
Isoiridomyrmecin
  synthesis
    *via* photocycloaddition, 667
    *via* photoisomerizations, 231
Isolinderalactone
  Cope rearrangement, 809
Isolobophytolide
  synthesis
    *via* photocycloaddition, 173
Isonitrin B
  synthesis
    *via* photocycloaddition, 167
Isopiperitenone
  synthesis
    *via* Cope rearrangement, 817
Isoprene
  [4 + 3] cycloaddition reactions, 603
  Diels–Alder reactions
    Lewis acid promoted, 339
  reaction with vinyl chromium carbene complexes, 1070
Isoprene, stannyl-
  Diels–Alder reactions, 337
Isopropenyl acetoacetate
  synthesis
    *via* retro Diels–Alder reactions, 558
Isopyrocalciferol
  synthesis
    *via* electrocyclization, 700
Isoquinolines, 5,6-dihydro-
  synthesis
    *via* FVP, 718
Isoquinolines, tetrahydro-
  synthesis
    *via* Diels–Alder reactions, 322
Isoquinolinium cations
  Diels–Alder reactions, 499, 500
Isoquinolinium cations, 2,4-dinitrophenyl-
  Diels–Alder reactions, 500
Isoquinolinodioxopyrroline
  Diels–Alder reactions, 323
Isoquinolinoid alkaloids
  tetracyclic
    synthesis *via* [2 + 2 + 2] cycloaddition, 1150
Isoxazoles
  Diels–Alder reactions, 491
Isoxazoles, 3-aryl-
  synthesis
    *via* retro Diels–Alder reactions, 584
Iterative rearrangements, 891–896

Japanese hop ether
  synthesis
    *via* Pauson–Khand reaction, 1051
Jasmone
  synthesis
    *via* Nazarov cyclization, 780
    *via* retro Diels–Alder reactions, 561
*cis*-Jasmone
  synthesis
    *via* [3 + 2] cycloaddition reactions, 308
Jasmone, dihydro-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 308
Jasmonic acid
  biosynthesis
    *via* Nazarov cyclization, 780
Jatropholones
  synthesis
    *via* Diels–Alder reaction, 342
Jatrophone, 2β-hydroxy-
  synthesis
    *via* [3 + 2] cycloaddition reactions, 311
Johnson–Faulkner rearrangement
  aldols, 839
Johnson ortho ester rearrangement
  allyl alcohols
    remote stereocontrol, 864
  variant of Claisen rearrangement, 839
Joubertiamine, 3-*O′-methoxy-4′-O*-methyl-
  synthesis
    stereocontrolled, *via* Eschenmoser rearrangement, 838
Juglone
  Diels–Alder reactions, 373, 376
Juncusol
  synthesis
    *via* retro Diels–Alder reaction, 572
Juvabione
  synthesis

    *via* Cope rearrangement, 821
Juvenile hormone
  synthesis
    *via* iterative rearrangements, 891

Kainic acid
  synthesis
    *via* Diels–Alder reaction, 468
α-Kainic acid
  synthesis
    *via* intramolecular ene reaction, 14
    *via* Ireland rearrangement, 843
Karahanaenone
  synthesis
    *via* Cope rearrangement, 803, 976
    *via* [4 + 3] cycloaddition, 603
Ketals, cyclopropenone
  vinylcarbene generation
    [4 + 3] cycloaddition reactions, 599
Ketene, dichloro-
  generation, 86
Ketene, diphenyl-
  reaction with benzoquinone, 86
  reaction with ethoxyacetylene, 732
Ketene, vinyl-
  synthesis
    *via* cyclobutenone, 675
Ketene acetals
  [2 + 2] cycloaddition reactions, 71
  Diels–Alder reactions, 461
  reactions with isocyanates, 103
  reaction with vinyl ethers, 684
Ketene acetals, bis(trimethylsilyl)-
  reaction with imines, 102
Ketene aminals
  reactions with isocyanates, 103
Ketene-*N*-methylimine, diphenyl-
  cycloaddition reactions
    metal catalyzed, 1195
Ketenes
  electrocyclization, 730–734
  intramolecular [2 + 2] cycloaddition, 1021
  reaction with carbonyl compounds
    chemoselectivity, 86
    regioselectivity, 86
    stereoselectivity, 87–89
  reaction with imines
    chemoselectivity, 92–99
    regioselectivity, 92–99
    stereoselectivity, 95–99
  synthesis
    *via* retro Diels–Alder reactions, 558
Ketenes, cyano-
  generation, 90
Ketenes, dimethyl-
  synthesis
    *via* retro Diels–Alder reactions, 558
Ketenes, diphenyl-
  [3 + 2] cycloaddition reactions
    with $\eta^1$-butynyliron complexes, 277
Ketenes, divinyl-
  Diels–Alder reactions, 395
Ketenes, vinyl-
  [2 + 2] cycloaddition
    1,3-dienes, 1020
  intramolecular cycloadditions, 1029
  synthesis
    *via* cyclobutenone ring opening, 688, 689
Ketenimines
  cycloaddition reactions, 113
  [3 + 2] cycloaddition reactions, 297
  reactions with Fischer carbene complexes, 1109
Keteniminium salts
  2-azetidiniminium salts from, 108–113
Keteniminium tetrafluoroborate, tetramethyl-
  β-lactams from, 112
Ketone, α-chlorodibenzyl
  reaction with furan
    [4 + 3] cycloaddition, 594
Ketone, methyl vinyl
  [3 + 2] cycloaddition reactions
    palladium catalyzed, 281
    with 1-methyl-1-(trimethylsilyl)allene, 277
  Diels–Alder reactions
    comparison of promoters, 345
    water promoted, 344
  ene reactions
    intermolecular, 3
Ketone enolates
  Michael additions, 1082
Ketones
  acyclic
    synthesis *via* retro Diels–Alder reactions, 573
  alkenic
    synthesis *via* Claisen rearrangement, 827
  alkylidenation
    dihaloalkane reagents, 1125
  alkynic
    cyclization, catalysts, 22
  bicyclic β,γ-unsaturated
    photoisomerizations, 222
  electron deficient
    Diels–Alder reactions, 432
  enolizable
    methylenation using Tebbe reagent, 1123
  1-methoxy-substituted cyclic β,γ-unsaturated
    photoisomerizations, 226
  methylenation
    Tebbe reagent, 1123
  monocyclic β,γ-unsaturated
    photoisomerizations, 222
  spirocyclic β,γ-unsaturated
    photoisomerizations, 222
  α,β-unsaturated
    ene reactions, 5
    synthesis *via* retro Diels–Alder reactions, 553, 573
  α,β;β′,γ′;δ,ε-unsaturated
    photoisomerizations, 229
  β,γ-unsaturated
    rearrangement, 216
  β,γ;β′,γ′-unsaturated
    photoisomerizations, 229
  γ,δ-unsaturated
    synthesis *via* Claisen rearrangement, 1004
Ketones, α-allyloxy
  Claisen rearrangement, 847
  enolates
    Claisen rearrangements, 1001
Ketones, allyl vinyl
  cyclization, 755–761
  Rupe rearrangement, 768
  synthesis

    *via* hydration of dienynes, 752
Ketones, α-bromoalkyl
  [4 + 3] cycloaddition reactions, 595
Ketones, α-bromobenzyl
  [4 + 3] cycloaddition reactions, 595
Ketones, cyclopropyl
  ring opening
    cyclopentene annulation, 925
Ketones, α,α′-dibromo
  [4 + 3] cycloaddition reactions, 603
Ketones, α,α′-dibromomethyl alkyl
  [4 + 3] cycloaddition reactions, 605
Ketones, α,α′-dihalo
  [4 + 3] cycloaddition reactions, 594, 603
Ketones, α,α′-divinyl
  cyclization, 755–761
    *in situ* generation, 766–770, 775–778
  photocyclization, 760
  ring closure
    2-cyclopentenone synthesis, 752
  silicon-directed cyclization, 761–766
  solvolysis
    cyclization, 770–775
Ketones, α-halo
  [4 + 3] cycloaddition reactions, 595
Ketones, hydroxy
  α,β-unsaturated
    Diels–Alder reactions, 359
Ketones, α-hydroxy
  Diels–Alder reactions
    intramolecular asymmetric, 543
Ketones, methyl vinyl
  ene reactions
    Lewis acid catalysis, 5
Ketones, β-silyl divinyl
  cyclization, 762
Ketones, tetrabromo
  [4 + 3] cycloaddition reactions, 603
Ketones, tetramethyldibromo
  [3 + 2] cycloaddition reactions
    with α-methylstyrene, 283
Ketones, tetrasubstituted dibromo
  [4 + 3] cycloaddition reactions, 603
Ketones, tribromo
  [4 + 3] cycloaddition reactions, 603
Ketones, β-(2-vinylcyclopropyl)
  α,β-unsaturated
    Cope rearrangement, 979–984
Keyhole limpet hemocyanin
  monoclonal antibodies
    Claisen rearrangement, 855
Khellin
  synthesis, 1096, 1098
Khellinone
  synthesis
    *via* cyclobutenone ring opening, 689
Khusimone
  synthesis
    *via* magnesium-ene reaction, 45

β-Lactams
  enantiopure
    synthesis *via* chiral ketenes or imines, 96
  synthesis, 1107
    *via* intramolecular photocycloaddition, 181
    *via* ketenes and carbonyls, 90
γ-Lactams, *N,O*-acetal-
  bicyclic
    Diels–Alder reactions, 372
β-Lactams, 3-alkylidene-
  synthesis
    *via* cycloaddition with CSI, 107
β-Lactams, α-amido-
  synthesis
    *via* Dane salts, 95
β-Lactams, 3-amino-
  synthesis
    *via* homochiral ketenes, 98
Lactic acid, ethyl ester, acrylate
  Diels–Alder reactions, 365
Lactic acid, ethyl ester, fumarate
  Diels–Alder reactions, 365
Lactones
  γ-amino-
    synthesis *via* [2 + 2 + 2] cycloaddition, 1138
  methylenation
    Tebbe reagent, 1123
  synthesis
    *via* [3 + 2] cycloaddition reactions, 297
  β,γ-unsaturated
    synthesis *via* [2 + 2 + 2] cycloaddition, 1138
β-Lactones
  synthesis
    *via* ketenes and carbonyls, 86
γ-Lactones
  synthesis
    *via* metal-catalyzed cycloaddition, 1196, 1200
Lactones, γ-hydroxy-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1138
Lactones, α-methylene-
  synthesis, 942
Lasiodiplodin
  synthesis
    *via* Diels–Alder reactions, 330
Laureacetal-C
  synthesis
    *via* intramolecular photocycloaddition, 180
Laurenene
  synthesis
    *via* photocycloaddition, 144, 662, 663
Lavendamycin
  synthesis
    *via* Diels–Alder reaction, 492
Leukotriene D, 5-deoxy-
  precursor synthesis
    *via* sulfoxide–sulfenate rearrangement, 890
Levoglucosenone
  Diels–Alder reaction, 350
Lewis acids
  promoters
    Diels–Alder reactions, 339–341
Ligularone
  synthesis
    *via* retro Diels–Alder reactions, 579
Lilac alcohol
  synthesis
    *via* [4 + 3] cycloaddition, 611
Linalool
  synthesis
    *via* retro Diels–Alder reaction, 555
Linalool, dehydro-

  ene reaction, 15
Linderalactone
  Cope rearrangement, 809
Lithium dialkylamide
  ester enolization
    Claisen rearrangement, 828
Lithium-ene reactions
  intramolecular, 37–46
Lithium enolates
  Claisen rearrangement, 847
Lithium phenylethynolate
  cycloaddition with carbonyls
    2-oxetanone synthesis, 116
Living polymers
  ring opening metathesis polymerization, 1120
Loganin, deoxy-
  synthesis
    *via* Diels–Alder reaction, 468
Loganin, 1-*O*-methyl-
  synthesis
    *via* Diels–Alder reactions, 363
Loganins
  aglucone 6-acetate
    synthesis *via* photoisomerization, 232
  biosynthesis, 468
  synthesis
    *via* [3 + 2] cycloaddition reactions, 310
    *via* photochemical cycloaddition, 129
Luciduline
  synthesis
    *via* Cope rearrangement, 814
    *via* Diels–Alder reaction, 351
Lumisantonin
  photochemistry, 730
Lumisterol
  synthesis
    *via* photochemical ring closure, 700
Lysergic acid
  synthesis
    *via* Diels–Alder reaction, 414

Macrocyclic compounds
  synthesis
    alkene metathesis, 1118–1120
Magnesium, 1-alkenyl-
  allylation, 32
Magnesium, 2-alkenyl-
  precursors
    synthesis for magnesium-ene reaction, 37
Magnesium bromide, 2,7-octadienyl-
  cyclization
    magnesium-ene reaction, 38
Magnesium chloride, (2-alkenyl)allyl-
  ene reactions, 43
Magnesium-ene reactions, 30
  intramolecular, 37–46, 59
  ring size, 60
Magnesium enolates
  Claisen rearrangement, 847
Maleic anhydride
  benzene irradiation
    fulvene trap, 646
  [3 + 2] cycloaddition reactions
    with $\eta^1$-allylpalladium complexes, 275
  Diels–Alder reactions
    Lewis acid promoted, 339
  ene reactions
    intermolecular, 2
Malonic acid, benzylidene-
  dimethyl ester
    [3 + 2] cycloaddition reactions, 302
Malonic acid, methylene-
  diesters
    synthesis *via* retro Diels–Alder reaction, 553
  dimenthyl ester
    Diels–Alder reactions, 356
  dimethyl ester
    cycloaddition reactions, 272
Malonic acid, thioxo-
  diethyl ester
    Diels–Alder reactions, 436
Malononitrile, benzylidene-
  cycloaddition reactions, 273
Matsutake alcohol
  synthesis
    *via* retro Diels–Alder reaction, 554
Meldrum's acid
  flash vapour pyrolysis, 732
Menthone
  photocycloaddition
    with furan, 170
Mercury salts
  catalysts
    Cope rearrangement, 802
Mercury-sensitized photoreactions
  di-π-methane rearrangement, 195
Mesitonitrile oxide
  cycloaddition reactions
    tropones, 626
Mesonaphthodianthrone
  synthesis
    *via* photolysis, 729
Mesoxylates
  *N*-acylimines
    Diels–Alder reactions, 405
  Diels–Alder reactions, 432
[2,2]Metacyclophane-4,9-diene, 15,16-dimethyl-
  synthesis
    *via* electrocyclization, 705
Metallacycles
  alkene metathesis, 1115
Metallacyclobutane, 2-methylene-
  [3 + 2] cycloaddition reactions, 293
Metallacyclopentadienes
  reactions with alkynes
    benzene synthesis, 1144
Metallacyclopentenes
  reactions with alkenes, 1142
Metallo-ene reactions, 29–60
  intermolecular, 30–37
  intramolecular, 37–59
  regioselectivity, 30, 60
  ring size, 59
  stereoselectivity, 30, 60
Methallyl cation
  [4 + 3] cycloaddition reactions, 597
β-Methallyl iodide
  generation of methallyl cation
    [4 + 3] cycloaddition reactions, 597
Methane, dimethylene-
  [3 + 2] cycloaddition reactions, 272–282
Methane, trimethylene-

complexes
  synthesis, 1107
  [4 + 3] cycloaddition reactions, 598
  1,3-diyl trapping reaction, 239
    stereoselectivity, 242
  reactions, 240
    regioselectivity, 240
  synthetic equivalents, 244
  synthons
    [3 + 2] cycloaddition reactions, 287–312
Methanimine
  synthesis
    *via* retro Diels–Alder reactions, 576
1,6-Methano[10]annulen-11-one
  synthesis
    *via* [6 + 4] cycloaddition, 623
2,4-Methanoproline
  synthesis
    *via* intramolecular photocycloaddition, 179
Methyl α-acetamidoacrylate
  ene reactions
    Lewis acid catalysis, 5
Methyl acrylate
  [3 + 2] cycloaddition reactions
    with electron deficient vinylcyclopropanes, 281
  Diels–Alder reactions, 461
    Lewis acid promoted, 339
    α-silapyran, 1074
  ene reactions
    intermolecular, 3
  reaction with iron carbonyl, 1131
  reaction with vinyl chromium carbene complexes, 1070
Methyl α-bromomethacrylate
  ene reactions
    Lewis acid catalysis, 5
Methyl crotonate
  Diels–Alder reactions
    Lewis acid promoted, 340
  reaction with Danishefsky's diene, 1072
Methyl α-cyanoacrylate
  ene reactions
    Lewis acid catalysis, 5
Methylenium cations, thioamido-
  Diels–Alder reactions, 504
Methylenomycin A, deepoxy-2,3-didehydro-
  synthesis
    *via* Nazarov cyclization, 780
Methylenomycin B
  synthesis
    *via* Nazarov cyclization, 780
    *via* nickel-ene reaction, 36
    *via* Pauson–Khand reaction, 1051
Methyl methacrylate
  Diels–Alder reactions
    Lewis acid promoted, 340
  ene reactions
    Lewis acid catalysis, 5
    thermal, 3
  reaction with cyclopentadiene, 1071
Methyl propiolate
  ene reactions, 6
    Lewis acid catalysis, 7
Methynolide
  synthesis
    *via* iterative rearrangements, 894
Michael additions
  α,β-unsaturated carbene complexes, 1081
Modhephene
  synthesis, 924
    *via* [3 + 2] cycloaddition reactions, 310
    *via* intramolecular ene reactions, 11, 2
    *via* Nazarov cyclization, 779
    *via* photocycloaddition, 666
    *via* photoisomerization, 233
Molybdenum catalysts
  alkene metathesis, *1118*
Molybdenum complexes, alkylidene-
  carbonyl alkylidenation, 1126
Molybdenum complexes, carbene
  chemistry, 1091
Monensin
  synthesis
    *via* Claisen rearrangement, 853
Monoclonal antibodies
  synthetic protein catalysts
    Claisen rearrangement, 855
Morphinans
  synthesis
    *via* benzocyclobutene ring opening, 693
Multifidene
  synthesis
    *via* Cope rearrangement, 806
    *via* retro Diels–Alder reactions, 563
Muscarine
  synthesis
    *via* [3 + 2] cycloaddition reactions, 286
    *via* [4 + 3] cycloaddition reactions, 605
Muscone
  synthesis
    *via* Raphael–Nazarov cyclization, 779
Muscopyridine
  synthesis
    *via* Raphael–Nazarov cyclization, 779
Muxone
  synthesis
    *via* cyclobutene ring expansion, 687
Mycophenolic acid
  synthesis
    *via* cyclobutenone ring opening, 689
    *via* electrocyclization, 732

Nanaomycin
  synthesis, 1096
    regioselective, 1094
Nanaomycin A
  synthesis
    *via* cyclobutenone ring opening, 690
    *via* metal-catalyzed cycloaddition, 1203
Naphthalene, 1,4-dihydro-
  photoisomerization, 197
*cis*-Naphthalene, 9,10-dihydro-
  synthesis
    *via* thermal isomerization, 716
*trans*-Naphthalene, 9,10-dihydro-
  photolysis, 716
Naphthalene, 1,8-divinyl-
  isomerization, 68
Naphthalene, octahydro-
  *cis*-fused
    synthesis *via* palladium-ene reaction, 50
Naphthalenes

    synthesis
        *via* Cope rearrangement, 809
Periselectivity
    cycloaddition reactions
        control, 617
        tropones, 620
    cyclopentadiene
        reaction with fulvenes, 626
[4]Peristylane
    synthesis
        *via* Diels–Alder reactions, 324
Petasalbine
    synthesis
        *via* retro Diels–Alder reactions, 579
α-Phellandrene
    photochemical isomerization, 738
Phenacyl sulfides
    photolysis
        thioaldehyde generation, 436

- Phenanthraquinone
  - photolysis
    - with benzophenone, 156
- Phenanthrene, 4-styryl-
  - photochemical irradiation, 729
- Phenanthrene, 4-vinyl-
  - photochemistry, 726
- Phenanthrenes
  - synthesis
    - *via* benzyne Diels–Alder reactions, 381
    - *via* electrocyclization, 720
- Phenanthrenes, dihydro-
  - synthesis
    - *via* electrocyclization, 718
    - *via* retro Diels–Alder reaction, 572
- Phenanthrenes, 9,10-dihydro-
  - synthesis
    - *via* photolysis, 723
- Phencyclone
  - cycloaddition reactions
    - cycloheptatriene, 632
- Phenol, *o*-allyl-
  - synthesis
    - *via* Claisen rearrangement, 834
- Phenols
  - synthesis
    - *via* Diels–Alder reactions, 329
- Phenyl isocyanate
  - [3 + 2] cycloaddition reactions
    - palladium-catalyzed, 281
- Phenylseleno etherification
  - intramolecular
    - lactones, 833
- Pheromones
  - synthesis
    - *via* alkene metathesis, 1117
    - *via* ene reaction, 8
    - *via* photocycloaddition, 165
- Phillips Triolefin Process
  - alkene metathesis, 1117
- Phoracantholide
  - synthesis
    - *via* Cope rearrangement, 808
- Phosphaalkenes
  - synthesis
    - *via* retro Diels–Alder reactions, 577
- Phosphine, isopropenyl-
  - synthesis
    - *via* retro Diels–Alder reactions, 560
- Phosphine, prop-1-enyl-
  - synthesis
    - *via* retro Diels–Alder reactions, 560
- Phosphine oxide, tri-*n*-butyl-
  - catalyst
    - Pauson–Khand reaction, 1048
- Phosphines, vinyl-
  - synthesis
    - *via* retro Diels–Alder reactions, 560
- Phosphites, tris(*o*-phenylphenyl)
  - co-catalyst
    - alkyne co-dimerization, 296
- Phosphonium bromide, vinyltriphenyl-
  - Diels–Alder reactions, 328
- Phosphonium salts, cyclopropyl-
  - cycloaddition reactions, 268
- Phosphonium salts, vinyl-
  - Diels–Alder reactions, 328
- Phosphonium tetrafluoroborate, ethoxycarbonylcyclopropyl-
  - cycloaddition reactions, 268
- Phosphonium ylides, allyloxytrimethylphenyl-
  - Claisen rearrangement, 830
- Phosphorus compounds
  - Diels–Alder reactions, 444
- Photocycloaddition reactions
  - 1,3-dienes, 635–638
  - enantioselectivity, 132
  - intermolecular, 125–132
    - regiochemistry, 125–127
  - intramolecular, 133–145
    - regioselectivity, 133–137
    - stereoselectivity, 137–145
  - stereochemistry, 128–132
- [2 + 2] Photocycloaddition reactions
  - copper catalysis, 147
- [3 + 2] Photocycloaddition reactions

  - di-π-methane, 193–213
  - fragmentations, 209
  - radical-type rearrangement, 208
  - 1,3-sigmatropic shift, 207
- Phthalic acid
  - dimethyl ester
    - synthesis *via* retro Diels–Alder reaction, 571
- Phthalide, 1,2-dihydro-
  - photolysis, 739
- Phyllanthocin
  - synthesis
    - *via* [3 + 2] cycloaddition reactions, 311
- Phyllocladane
  - synthesis
    - *via* [3 + 2] cycloaddition reactions, 311
- Phyllostine
  - synthesis
    - *via* retro Diels–Alder reactions, 564
- β-Pinene
  - ene reactions, 2
- Pipecolic acid
  - synthesis
    - *via* Ireland rearrangement, 843
- Piperidines
  - synthesis
    - *via* palladium-ene reactions, 51
- α-Pipitzol
  - synthesis
    - *via* photocycloaddition, 660
- Platelet activating factor
  - antagonist ligands
    - synthesis *via* Paterno–Büchi reaction, 152
- Platinum complexes, $\eta^1$-allyl-
  - [3 + 2] cycloaddition reactions
    - tetracyanoethylene, 275
- Platinum-ene cyclizations, 56–59
- Plumbagin
  - synthesis
    - *via* retro Diels–Alder reaction, 564
- Podophyllotoxin
  - synthesis
    - *via* benzyne cyclization, 692

Poitediol
  synthesis
    *via* alkynylvinylcyclobutanol rearrangement, 1026
    *via* Cope rearrangement, 806
Polycyclopentanoids
  synthesis
    *via* magnesium-ene reaction, 40
Polyether antibiotics
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 840
*cis*-1,4-Polyisoprene
  photolysis
    with benzophenone, 161
Polymers
  monodispersed
    synthesis, 1121
  synthesis
    *via* alkene metathesis, 1120–1122
Polynorbornene
  synthesis
    *via* ring opening metathesis polymerization, 1121
Polypentenamer
  synthesis
    *via* ring opening metathesis polymerization, 1120
Polyquinanes
  synthesis
    *via* Nazarov cyclization, 779
    *via* photoisomerizations, 226
Poly(vinylbenzophenone)
  photocycloaddition reactions
    alkenes, 161
Porphyrin, octamethyl-
  synthesis
    *via* Diels–Alder reaction, 492
Precalciferol
  synthesis
    *via* photochemical ring opening, 700
Precapnelladiene
  synthesis
    *via* Claisen rearrangement, 831
Preclavulone A
  biosynthesis
    *via* Nazarov cyclization, 780
Precocene, 7-ethoxy-
  synthesis, 1096, 1098
Prefulvene
  formation
    *via* benzene irradiation, 649
Prelog–Djerassi lactone
  synthesis
    *via* [4 + 3] cycloaddition, 611
Prephenic acid
  synthesis
    *via* Diels–Alder reactions, 324
Previtamin D
  synthesis
    *via* photolysis, 737
Prezizaene
  synthesis
    *via* Cope rearrangement, 989
Prezizanol
  synthesis
    *via* Cope rearrangement, 989
Prodigiosin
  synthesis
    *via* Diels–Alder reaction, 492
Progesterone, 11-keto-
  synthesis
    *via* Cope rearrangement, 790
Proline, *N*-acryloyl-
  benzyl ester
    Diels–Alder reaction, 365
  Diels–Alder reactions, 366
Propadienethione
  synthesis
    *via* retro Diels–Alder reactions, 575
Propanal, 2-phenyl-
  reaction with methyl pyrrolidine complex anions, 1080
Propane, 1,3-diiodo-
  [3 + 2] cycloaddition reactions
    copper-catalyzed, 282
Propane, 1,3-disubstituted 2-methylene-
  bifunctional conjunctive reagent, 298
2-Propanone, 1,3-dibromo-1-phenyl-
  [4 + 3] cycloaddition reactions, 605
Propargyl alcohol
  trimerization, 1145
Propargyl aldehyde
  cycloaddition reactions
    carbene complexes, 1073
Propargylamine
  divinyl ketone from, 753
Propargyl cation
  [4 + 3] cycloaddition reactions, 598
Propargylic acetals
  cyclization, 769
[1.3.4]Propellane
  synthesis
    *via* Diels–Alder reaction, 372
[3.3.3]Propellanes
  synthesis
    *via* intramolecular ene reactions, 11, 21
    *via* photoisomerization, 233
Propellanes
  synthesis
    *via* Cope rearrangement, 814
    *via* [3 + 2] cycloaddition reactions, 310
    *via* cyclopropane ring opening, 924
    *via* photocycloaddition, 666
[4.2.2]Propella-2,4,7,9-tetraene
  isomerization
    *via* retro Diels–Alder reactions, 585
Propene
  disproportionation, 1116
Propene, 2-chloromethyl-3-chloro-
  bifunctional conjunctive reagent, 299
Propene, 2-chloromethyl-3-trimethylsilyl-
  bifunctional conjunctive reagent, 299
Propene, 3-diazo-
  [3 + 2] cycloaddition reactions
    alkynyl carbene complexes, 1070
Propene, 1,3-diphenyl-
  photoisomerization, 208
Propene, 1-ethoxy-
  Diels–Alder reactions, 461, 473
Propene, 3-iodo-2-(trimethylsilyl)methyl-
  [4 + 3] cycloaddition reactions, 599
  trimethylenemethane synthetic equivalent, 246
Propene, 2-methoxy-
  Eschenmoser rearrangement, 891
Propene, methylaryl-

  - photoisomerization, 197
- Propene, 3-phenyl-
  - photoisomerization, 197
- Propenes, 3-aryl-
  - Pauson–Khand reaction, 1045
- 2-Propenoic acid, 3-(3-methylenecyclopentyl)-
  - methyl ester
    - synthesis *via* metal-catalyzed cycloaddition, 1192
- 2-Propen-1-ol, 2-(trimethylsilyl)methyl-
  - bifunctional conjunctive reagent, 299
- 2-Propen-1-yl, 2-(trimethylsilyl)methyl-
  - acetate

    - *via* cyclopropane ring opening, 924
    - *via* electrocyclization, 771
    - *via* Pauson–Khand reaction, 1051
- 6-Protoilludene
  - synthesis
    - *via* magnesium-ene reaction, 40
- Protoporphorins
  - reaction with tetracyanoethylene, 71
- Provitamin D
  - photochemical ring opening, 700
  - photolysis, 737
- Pseudocytidine
  - synthesis
    - *via* [4 + 3] cycloaddition, 611
- Pseudoguaiane
  - synthesis
    - *via* photocycloaddition, 669
- Pseudoguaianolides
  - synthesis
    - *via* Pauson–Khand reaction, 1052
- Pseudoisocytidine
  - synthesis
    - *via* [4 + 3] cycloaddition, 611
- Pseudomonic acid
  - synthesis
    - *via* Claisen–Claisen rearrangement, 888
- Pseudomonic acid A
  - synthesis
    - *via* Diels–Alder reaction, 435
- Pseudopericyclic reactions
  - hetero electrocyclization, 741
- Pseudouridine
  - synthesis
    - *via* [4 + 3] cycloaddition, 611
- Pseudouridine, 2-thio-
  - synthesis
    - *via* [4 + 3] cycloaddition, 611
- Pulo'upone
  - synthesis
    - *via* Diels–Alder reactions, 364
    - *via* intramolecular Diels–Alder reaction, 545
- Pumiliotoxin C
  - synthesis
    - *via* Diels–Alder reactions, 333, 360
- Punaglandins
  - synthesis
    - *via* retro Diels–Alder reactions, 562
- 2*H*-Pyran-2-one, 3,4-dihydro-4,4-dimethyl-
  - photolysis
    - with benzoquinone, 156
- 4-Pyranones, tetrahydro-
  - cyclization, 766
- α-Pyrans
  - synthesis
    - *via* photolysis, 741
- Pyrans, dihydro-
  - [2 + 2] cycloaddition reactions
    - methyl tetrolate, 1067
  - Pauson–Khand reaction, 45, 1048
  - synthesis
    - *via* Diels–Alder reaction, 435
- Pyrans, 3,4-dihydro-
  - reaction with dimethyl acetylenedicarboxylate
    - dihydrooxacine synthesis, 687
  - reaction with isocyanates
    - glycal synthesis, 108

  - synthesis
    - *via* retro Diels–Alder reactions, 582
- Pyrazole, 4-(2′-styryl)-

synthesis
    *via* retro Diels–Alder reactions, 584
5-Pyrazolones, 4-arylidene-
  Diels–Alder reactions, 454
Pyrene, 15,16-dimethyldihydro-
  electrocyclization, 705
Pyrene, tetrahydro-
  synthesis
    *via* photolysis, 728
Pyrenes
  synthesis
    *via* electrocyclization, 720
Pyrenochaetic acid A
  synthesis
    *via* retro Diels–Alder reaction, 571
Pyrethrin-I
  pyrolysis, 717
Pyridazines
  Diels–Alder reactions, 491
Pyridine, 2-alkylthio-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1154
Pyridine, 2-amino-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1154
Pyridine, bis(5-hexynyl)methyl-
  synthesis
    *via* cycloaddition, 1154
Pyridine, cyanodihydro-
  dimerization, 64
Pyridines
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1152–1155
    *via* Diels–Alder reactions, 412, 416, 491
    *via* metal catalysts, 1153
    *via* retro Diels–Alder reactions, 583
Pyridines, 2-alkyl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1152
Pyridines, 2-aryl-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1152
Pyridines, 2-(ω-cyanoalkyl)-
  synthesis
    *via* cocycloaddition, 1155
Pyridines, 1,2-dihydro-
  Diels–Alder reactions
    acyl nitroso compounds, 420
    nitrosobenzene, 418
  synthesis
    *via* hetero electrocyclization, 741
Pyridines, 1,4-dihydro-
  synthesis
    *via* retro Diels–Alder reactions, 583
Pyridines, 5,6-dihydro-
  synthesis
    *via* retro Diels–Alder reactions, 583
Pyridines, 2-imino-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1156
Pyridines, tetrahydro-
  carbene complexes
    reactions with diphenylacetylene, 1105
  synthesis
    *via* Diels–Alder reactions, 404, 406
Pyridine-2-thiones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1158
2-Pyridone, *N*-methyl-
  photodimerization, 637
2-Pyridones
  photodimerization, 637, 638
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1155–1157
Pyridoxine
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1154
Pyridyl betaine, nitro-
  cycloaddition reactions
    fulvenes, 630
Pyridylnitriles
  cycloaddition reactions, 1152
3,4-Pyridyne
  Diels–Alder reactions, 384
Pyrimidinediones
  synthesis

  - Diels–Alder reactions, 473
- Quinone, 1,2-dicyano-4,5-dichloro-
  - cycloaddition reactions, 273

Quinone epoxides
  synthesis
    *via* retro Diels–Alder reactions, 563
*o*-Quinone methides
  Diels–Alder reactions, 468
Quinones
  synthesis
    *via* electrocyclization, 733
    *via* metal-catalyzed cycloaddition, 1202–1204
*o*-Quinones
  Diels–Alder reactions, 468
*p*-Quinones
  Diels–Alder reactions, 330, 341

Radio frequency plasma reactions
  di-π-methane rearrangements, 195
Rearrangements
  charge-accelerated
    small rings, 999–1033
  vinylcyclopropanes, 899–965
Reserpine
  synthesis
    *via* Cope rearrangement, 814
    *via* Diels–Alder reaction, 341
Retigeranic acid
  synthesis
    *via* photocycloaddition, 664
13-*cis*-Retinal, 13-*t*-butyl-
  Schiff base
    heterocyclization, 742
Retroaddition reactions
  cyclobutanes, 64
Retroelectrocyclization
  triene synthesis, 737–740
Retronecine
  synthesis
    *via* Diels–Alder reaction, 421
Rhenium catalysts
  alkene metathesis, 1118
Rhodacyclopentadienes
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1135
Rhodium catalysts
  Cope rearrangement, 802
D-Ribose, 2-deoxy-
  synthesis, 263
Ring expansion
  *via* Claisen rearrangement, 831
  iterative sigmatropic processes, 894–896
Ring opening metathesis polymerization
  alkene metathesis, 1120
Ring opening reactions
  cyclobutenes, 675–694
    two-carbon ring expansion, 686–688
  cyclobutenones, 688–691
Rocaglamide
  synthesis
    *via* [3 + 2] cycloaddition reactions, 311
Rosettane
  synthesis
    *via* photocycloaddition, 662, 663
Royleanone
  synthesis
    *via* metal-catalyzed cycloaddition, 1203
Rudmollin
  synthesis
    *via* photocycloaddition, 669
Rule of five
  intramolecular photocycloaddition reactions, 133
Rupe rearrangement
  alkynic alcohols, 768
Ruthenium catalysts
  alkene metathesis, 1118

β-Santalene
  synthesis
    *via* Diels–Alder reactions, 358
Sarkomycin
  synthesis
    *via* [3 + 2] cycloaddition reactions, 308
    *via* cyclopropanes, 907
    *via* Pauson–Khand reaction, 1051
    *via* retro Diels–Alder reaction, 560, 568
Sarracenin
  synthesis
    *via* photocycloaddition, 129, 166
Scopine
  synthesis
    *via* [4 + 3] cycloaddition, 609
Selenoaldehydes
  Diels–Alder reactions, 442
  synthesis, 442
Selenocarbonyl compounds
  Diels–Alder reactions, 442
Selenoketones
  synthesis, 442
Selenophenes
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1139
β-Selinene
  synthesis
    *via* oxyanion-accelerated rearrangement, 1020
Semibullvalene
  synthesis
    *via* photoisomerization, 194, 204
Semibullvalenes, dihydro-
  synthesis
    *via* retro electrocyclization, 737
Senepoxyde
  synthesis
    *via* retro Diels–Alder reactions, 563
Senoxydene
  precursor
    synthesis *via* intramolecular ene reactions, 22
Sequential rearrangements, 876–891
Sesamin
  synthesis
    *via* Diels–Alder reaction, 468
Sesamolin
  synthesis
    *via* Diels–Alder reaction, 468
Sesquinorbornene
  reaction with methanol, 74
Sesquiterpenes
  synthesis
    *via* photoisomerizations, 230
Seven-membered carbocycles
  synthesis
    *via* [4 + 3] cycloadditions, 593
Seychellene
  synthesis
    *via* Diels–Alder reactions, 329

Shell Higher Olefin Process
  alkene metathesis, 1117
Shikimic acid
  synthesis
    *via* Diels–Alder reactions, 335, 360, 363
Shikimic acid pathway
  Claisen rearrangement, 855
Showdomycin
  synthesis
    *via* [4 + 3] cycloaddition, 611
Sigmatropic rearrangements
  carbene complexes, 1075
1,3-Sigmatropic rearrangements
  allylic alcohols, 1001
  aza-anion accelerated, 1003
  oxyanion-accelerated
    stereochemistry, 1002
1,5-Sigmatropic rearrangements
  carbanion-accelerated, 1005
  oxyanion-accelerated, 1003
Silabarrelene
  photorearrangement, 199
7-Silabicyclo[2.2.2]octadiene
  thermolysis
    retro Diels–Alder reaction, 587
Silane, 2-acetoxymethyl-3-allyltrimethyl-
  trimethylenemethane synthetic equivalent, 244
Silane, allyltrimethyl-
  ene reactions, 2
Silane, (iodomethyl)trimethyl-
  reaction with sulfonyl carbanions, 1014
Silane, (α-oxyallyl)-
  reaction with benzonitrile oxide, 262
Silane, 1-phenylthiovinyl-
  Nazarov cyclization, 778
Silane, 2-phenylthiovinyl-
  Nazarov cyclization, 778
Silane, vinyltrichloro-
  ene reactions
    thermal, 3
Silane, vinyltrimethyl-
  ethylene equivalent
    alkene acylation, 777
Silanes
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
Silanes, acyl-
  reaction with sulfonyl carbanions, 1014
  synthesis
    *via* Claisen rearrangement, 850
Silanes, allyl-
  [4 + 3] cycloaddition reactions, 598
  reaction with vinyloxiranes
    regioselectivity, 936
  synthesis
    *via* [3 + 2] cycloaddition reactions, 304
Silanes, dienyl-
  synthesis
    *via* zinc-ene reactions, 32
Silanes, vinyl-
  divinyl ketones from, 777
Silanones
  generation
    *via* retro Diels–Alder reaction, 587
2-Silapropene, 2-methyl-
  synthesis
    *via* retro Diels–Alder reaction, 587
2-Silapyrans
  Diels–Alder reaction, 587
    methyl acrylate, 1074
Silasemibullvalene
  synthesis
    *via* photoisomerization, 199
Silenes
  generation
    *via* retro Diels–Alder reaction, 587
Silica gel
  catalyst
    Pauson–Khand reaction, 1056
Silphinene
  synthesis
    *via* Nazarov cyclization, 779
    *via* photocycloaddition, 662
Silphiperfol-5-ene
  synthesis
    *via* photocycloaddition, 664
Silphiperfol-6-en-5-one
  synthesis
    *via* photoisomerization, 232
Silver salts
  catalysts
    Cope rearrangement, 802
*C*-Silylation
  Claisen rearrangements
    competition, 850
Silyl carbonates
  synthons
    [3 + 2] cycloaddition reactions, 304
Silylimines, *N*-trimethyl-
  reaction with silylketene acetals, 102
Silylketene acetals
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
β-Sinesal
  synthesis
    *via* tandem Claisen–Cope rearrangement, 878
Sinularene
  synthesis
    *via* Cope rearrangement, 989
    *via* magnesium-ene reaction, 41
Sinularene, 12-acetoxy-
  synthesis
    *via* magnesium-ene reaction, 41
α-Skytanthine
  synthesis
    *via* magnesium-ene reaction, 41
δ-Skytanthine
  synthesis
    *via* magnesium-ene reaction, 41
Slaframine
  synthesis
    *via* Diels–Alder reaction, 414
Small ring compounds
  cycloaddition reactions
    metal-catalyzed, 1185–1204
Sodium enolates
  Claisen rearrangement, 847
*threo*-Sphingosine
  synthesis
    *via* intramolecular Diels–Alder reaction, 425
Sphondin
  synthesis, 1096, 1099

    regioselective, 1094
Spiro[*n*,4]alkenones
  synthesis
    *via* [3 + 2] cycloaddition reactions, 285
Spiroazepinedione
  synthesis
    *via* intramolecular photocycloaddition, 181
Spirocyclobutanone
  annulation
    *via* ring expansion, 919
  synthesis
    *via* rearrangement of vinylcyclopropane, 919
Spiro[2.4]hepta-4,6-diene
  cycloaddition reactions
    tropones, 621
Spiro[2.4]heptane, 2-methylene-
  synthesis
    *via* metal-catalyzed cooligomerization, 1195
Spiro[4.11]hexadecenone
  synthesis
    *via* [3 + 2] cycloaddition reactions, 285
Spiro[3.5]nonanone, 5-methylene-
  divinylcyclobutanols from, 1028
Squalene
  photocrosslinking reactions
    poly(vinylbenzophenone), 161
  synthesis
    *via* iterative rearrangements, 892
Squaric acid
  dialkyl esters
    cyclobutenones from, 689
Stannanes
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
Stannanes, allyl-
  [3 + 2] cycloaddition reactions
    with acyliron complexes, 277
  reaction with vinyloxiranes
    regioselectivity, 936
Stannanes, cyclohexenyl-
  synthesis
    *via* Diels–Alder reaction, 335
Steganone
  synthesis
    *via* cyclobutene ring expansion, 687
Steroids
  A-ring aromatic
    synthesis *via* [2 + 2 + 2] cycloaddition, 1151
  B-ring aromatic
    synthesis *via* [2 + 2 + 2] cycloaddition, 1151
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
Stilbene, *o*-bromo-
  photocyclization, 724
Stilbenes
  photocyclization, 723
    bornyl fumarate, 132
Stilbestrol, diethyl-
  photolysis, 723
Streptonigrin
  synthesis
    *via* Diels–Alder reaction, 406, 492
Strigol
  synthesis
    *via* Raphael–Nazarov cyclization, 779
Styrene, α-cyclopropyl-
  [3 + 2] cycloaddition reactions
    with 2,4-dibromopentan-3-one, 283
Styrene, *cis*-β-deuterio-
  [3 + 2] cycloaddition reactions
    iron catalyzed, 285
Styrene, *p*-methoxy-
  [2 + 2] cycloaddition reactions, 73
  reaction with tetracyanoethylene, 71
    solvent effects, 75
Styrene, α-methyl-
  [3 + 2] cycloaddition reactions
    with tetramethyldibromo ketones, 283
Styrene, *trans*-β-methyl-*p*-methoxy-
  reaction with tetracyanoethylene
    solvent effects, 76
    thermochemistry, 76
Styrene, trifluoro-
  dimerization, 64
Styrenes
  cyclobutanones from, 1087
  dimerization, 63
  Pauson–Khand reaction, 1045
Succinimide, *N*-methyl-2-hydroxy-
  Diels–Alder reactions, 365
Succinimides, *exo*-methylene-
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1141
Succinonitrile, diimino-
  Diels–Alder reactions, 486
Sugars, branched-chain
  synthesis
    *via* Paterno–Büchi reaction, 158
Sulfenes
  Diels–Alder reactions, 440–442
Sulfide, bis(α-bromobenzyl)
  dehydrogenation
    ylide generation for [4 + 3] cycloaddition, 600
Sulfides, vinyl
  Diels–Alder reactions, 326
  Paterno–Büchi reaction
    with benzophenone, 160
Sulfine, α-chloro-
  Diels–Alder reactions, 441
Sulfines
  Diels–Alder reactions, 440–442
Sulfines, α-oxo-
  Diels–Alder reactions, 441
Sulfinic acids, allylic
  retro-ene reactions, 424
*N*-Sulfinyl dienophiles
  Diels–Alder reactions, 422
    intramolecular, 425
Sulfonamides, homoallylic
  synthesis
    *via* retro-ene reactions, 425
Sulfonamides, *N*-sulfinyl-
  Diels–Alder reactions
    dienes, 403
Sulfone, ethynyl *p*-tolyl
  ene reactions
    Lewis acid catalysis, 8
Sulfone, methyl α-bromovinyl
  Diels–Alder reactions, 324
Sulfones, acetoxyphenyl-
  *o*-quinodimethane precursor
    Diels–Alder reactions, 392

Sulfones, allenyl
  hetero-Cope rearrangement, 1004
Sulfones, α-hydroxy-
  *o*-quinodimethane precursors
    Diels–Alder reactions, 389
Sulfones, vinyl
  Diels–Alder reactions, 324
Sulfoxide, chiral vinyl
  [3 + 2] cycloaddition reactions
    asymmetric induction, 301
Sulfoxides, vinyl
  Diels–Alder reactions, 324, 369–371
  Michael-type addition
    tertiary allylic alcohols, 830
Sulfur-based rearrangements, 889–891
Sulfur dioxide
  extrusion
    diene synthesis *via* retro Diels–Alder reaction, 567
Sulfur ylides
  sigmatropic rearrangement, 894
Sultams, *N*-acyl-
  Diels–Alder reactions
    intramolecular asymmetric, 543
Sultams, *N*-crotonyl-
  Diels–Alder reactions, 365
Sultams, *N*-enoyl-
  Diels–Alder reactions, 365

Tandem rearrangements, 876–891
Tantalum catalysts
  alkene metathesis, 1118
  alkylidenation
    carbonyl compounds, 1122, 1125
Tartaric acid, monoacyl-
  catalyst
    Diels–Alder reactions, 377
Taxanes
  synthesis
    *via* Cope rearrangement, 796
    *via* [4 + 4] cycloaddition, 640
Tebbe reagent
  allyl vinyl ethers, 830
  methylenation, 1122
  reaction with norbornene, 1121
  synthesis, 1124
Teloidine
  synthesis
    *via* [4 + 3] cycloaddition, 609
Terephthalic acid
  dimethyl ester
    synthesis *via* retro Diels–Alder reaction, 571
Terpenes
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
    *via* photoisomerizations, 230
Terrein
  synthesis
    *via* retro Diels–Alder reactions, 561
Tetracyclines
  synthesis
    *via* oxyanion-accelerated rearrangement, 1022
Tetracyclone
  benzyne assay
    Diels–Alder reaction, 380
Tetracyclo[4.3.0.0$^{2,4}$.0$^{3,7}$]non-8-ene
  cycloaddition reactions, 1187
Tetracyclo[3.3.0.0$^{2,8}$.0$^{4,6}$]octane
  synthesis
    *via* metal-catalyzed cycloaddition, 1187
Tetracycloundecanone
  *cis,syn,cis*
    synthesis *via* photoisomerization, 233
Tetralin, 5-nitro-
  synthesis
    *via* electrocyclization, 719
Tetralone
  synthesis
    *via* electrocyclization, 719
α-Tetralones
  synthesis
    *via* oxyanion-accelerated rearrangement, 1022
    *via* thermal ring opening, 711
1,4-Tetramethylene diradical
  alkene dimerizations, 72
Tetrazine
  Diels–Alder reactions, 411
Tetrazine, 3,6-diphenyl-
  cycloaddition reactions
    fulvenes, 627
Tetrazines
  Diels–Alder reactions, 413
1,2,4,5-Tetrazines
  Diels–Alder reactions, 491
Tetrolic acid, methyl ester
  [2 + 2] cycloaddition reactions, 1067
  cycloaddition reactions with chromium propynyl complexes, 1072
  reaction with trimethylsilyldiazomethane, 1070
Tetronates
  synthesis
    *via* Ireland silyl ester enolate rearrangement, 841
β-Tetronic acids
  α-allylation
    *via* Claisen rearrangement, 832
Thiabutadienes
  cationic
    Diels–Alder reactions, 504–507
  Diels–Alder reactions, 469
Thiacyclooctene
  sigmatropic rearrangement, 896
Thiadiazolidines
  synthesis
    *via* Diels–Alder reactions, 426
Thiazine 1-imine, 3,6-dihydro-
  synthesis
    *via* Diels–Alder reactions, 422
Thiazine imines, dihydro-
  Diels–Alder reactions, 426
Thiazine 1-oxide, 3,6-dihydro-
  synthesis
    *via* Diels–Alder reactions, 422, 424
Thiazine oxides, dihydro-
  Diels–Alder reactions, 424
Thiazines
  cycloaddition reactions
    acid chlorides, 92
4*H*-1,3-Thiazinium salts, 5,6-dihydro-
  synthesis
    *via* Diels–Alder reactions, 504
Thiazoles
  Diels–Alder reactions, 491
Thiazolines

  cycloaddition reactions
    acid chlorides, 92
2-Thieniumbutadienes
  Diels–Alder reactions, 504
Thienium salts
  Diels–Alder reactions, 439
Thienium salts, aryl-
  Diels–Alder reactions, 504
Thieno[3,4-*b*]furan
  synthesis
    *via* retro Diels–Alder reactions, 584
Thietanes, 2-imino-
  synthesis
    *via* ketenimines, 114
2-Thietanones
  synthesis
    *via* ketenes and carbonyls, 89
Thiirane, vinyl-
  rearrangement, 909, 931
Thioacrolein
  synthesis
    *via* retro Diels–Alder reaction, 575
Thioacrylamide, *N*,*N*-dimethyl-
  synthesis
    *via* retro Diels–Alder reaction, 556
Thioacrylamides
  synthesis
    *via* retro Diels–Alder reaction, 556
Thioaldehydes
  Diels–Alder reactions, 436
  *S*-oxides
    synthesis *via* retro Diels–Alder reactions, 575
Thioamides
  α,β-unsaturated
    reactivity
Thiobenzophenone
  reactions with ketenimines, 114
Thiocarbonyl compounds
  Diels–Alder reactions, 435–442
Thio-Claisen rearrangement, 889
Thio compounds
  α,β-unsaturated
    synthesis *via* retro Diels–Alder reaction, 556
Thioesters
  Diels–Alder reactions, 438
Thioformaldehyde
  synthesis
    *via* retro Diels–Alder reactions, 575
Thioketenes
  cycloaddition reactions, 115
  synthesis
    *via* retro Diels–Alder reactions, 575
Thioketones
  Diels–Alder reactions, 436
  α,β-unsaturated acyclic
    synthesis *via* retro Diels–Alder reaction, 556
β-Thiolactones
  synthesis
    *via* ketenes and carbonyls, 89
Thiolen-2-one-5-spiro-5′-thiolen-4′-one
  synthesis
    *via* metal-catalyzed cycloaddition, 1200
Thionitroso compounds
  Diels–Alder reactions, 422
Thiophene, 2,3-dimethylene-
  dimerization
    *via* [4 + 4] cycloaddition, 639
Thiophene dioxide, 2-ethyl-5-methyl-
  cycloaddition reactions
    fulvenes, 628
Thiophene dioxide, 2-substituted 2,5-dihydro-
  thermolysis, 567
Thiophenes
  photocycloaddition reactions
    with benzaldehyde, 176
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1139
Thiophosgene
  Diels–Alder reactions, 439
2*H*-Thiopyran, 3,4-dihydro-
  synthesis
    *via* Diels–Alder reaction, 469
Thiopyran-2-thiones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1158
Thiosphondin
  synthesis, 1096
Thromboxane $A_2$
  analog
    synthesis *via* intramolecular photocycloaddition, 180
  synthesis
    *via* [4 + 3] cycloaddition, 605
    *via* Paterno–Büchi reaction, 151
Thromboxane $B_2$
  synthesis
    stereocontrolled, *via* Eschenmoser rearrangement, 837
Thromboxanes
  synthesis
    *via* [4 + 3] cycloaddition, 612
α-Thujaplicin
  synthesis
    *via* [4 + 3] cycloaddition, 609
β-Thujaplicin
  synthesis
    *via* [4 + 3] cycloaddition, 609
Tigliane diterpenoids
  synthesis
    *via* Cope rearrangement, 984
Tin, allyltributyl-
  [3 + 2] cycloaddition reactions
    with acyliron complexes, 277
Titanabicycles
  generation, 1171
Titanacyclic compounds
  bicyclization, 1169
Titanium, dialkoxy-
  chiral catalysts
    Diels–Alder reactions, 376
Titanium alkynides
  reactions with epoxides, 936
Titanium aluminum methylene
  Tebbe reagent
    alkylidenation, 1122
Titanium catalysts
  alkene metathesis, 1118
  alkylidenation
    carbonyl compounds, 1122
  bicyclization
    enynes, 1169
Titanium complexes, alkenyl-

  hydroalumination, 1124
Titanium oxametallacycles
  carbonyl methylenation, 1122
Titanium propionate, 3,3,3-trichloro-
  synthesis, 1200
Titanocene
  benzyne complex
    synthesis, 1174
  diphenylacetylene complex
    synthesis, 1174
α-Tocopherol
  synthesis
    *via* iterative Claisen rearrangement, 892
Toluene
  photocycloaddition reactions
    with cyclooctene, 655
*p*-Toluenesulfonamide, *N*-sulfinyl-
  Diels–Alder reactions, 424
Toluenesulfonyl isocyanates
  [3 + 2] cycloaddition reactions
    with $\eta^1$-allyliron complexes, 275
  reaction with dihydropyrans
    glycal synthesis, 108
Torreyal
  synthesis
    *via* tandem Claisen–Cope rearrangement, 879
Transition metal complexes
  carbenes
    cycloaddition reactions, 1065–1113
  Claisen rearrangement
    catalysis, 850
Transition metal complexes, methyl pyrrolidine
  alkylation, 1076
Transition metals
  catalysts
    cycloaddition reactions, 271–312
Transition metals, alkylidene-
  alkene metathesis, 1118
Transition states, boat-like
  Diels–Alder reactions
    decatrienones, 539–543
Triazines
  synthesis
    *via* Diels–Alder reactions, 412
1,2,3-Triazines
  Diels–Alder reactions, 491
1,2,4-Triazines
  Diels–Alder reactions, 491
1,3,5-Triazines
  Diels–Alder reactions, 491
Triazinetriones
  synthesis
    *via* [2 + 2 + 2] cycloaddition, 1158
Triazolinedione
  cycloaddition reactions, 206
1,2,4-Triazoline-3,5-dione, 4-phenyl-
  Diels–Alder reactions, 428
1,2,4-Triazoline-3,5-diones
  Diels–Alder reactions, 429
Trichodiene
  synthesis
    *via* Diels–Alder reaction, 338
    *via* Nazarov cyclization, 758
Trichoviridine
  metabolite
    synthesis *via* photocycloaddition, 167
Tricosene
  synthesis
    *via* alkene metathesis, 1118
Tricyclic compounds
  Cope rearrangements, 818
Tricyclo[5.2.1.$0^{4,10}$]decane
  synthesis
    *via* Pauson–Khand reaction, 1058
Tricyclo[5.2.1.$0^{2,6}$]decane, 4-allylidene-
  synthesis
    *via* metal-catalyzed codimerization, 1190
Tricyclo[5.2.1.$0^{2,6}$]decane, 4-methylene-3-vinyl-
  synthesis
    *via* metal-catalyzed codimerization, 1190
Tricyclo[5.2.1.$0^{4,10}$]decane-2,5,8-trione
  synthesis
    *via* Pauson–Khand reaction, 1062
Tricyclodecenols, *exo*-methylene-
  synthesis
    *via* retro Diels–Alder reactions, 562
Tricyclo[5.3.0.$0^{2,6}$]dec-4-en-3-ones
  synthesis
    *via* Pauson–Khand reaction, 1046
Tricyclo[3.1.0.$0^{2,4}$]hexane, 3,3,6,6-tetramethyl-
  synthesis
    *via* metal catalyzed cyclodimerization, 1197
Tricyclo[4.3.0.$0^{2,5}$]non-3-ene
  synthesis
    *via* photolysis, 737
Tricyclo[3.2.2.$0^{2,4}$]non-6-ene-8,9-dione
  irradiation, 713
Tricyclo[4.2.1.$0^{2,5}$]non-7-enes
  synthesis
    *via* cycloaddition of quadricyclane, 1187
*syn*-Tricyclo[4.2.0.$0^{2,5}$]octa-3,7-dienes
  synthesis
    *via* isomerization of cubenes, 1188
Tricyclo[3.3.0.$0^{2,8}$]octane-4,7-diones
  photoisomerizations, 227
Tricyclo[3.3.0.$0^{2,8}$]octan-3-one
  synthesis
    *via* photoisomerization, 200
*exo*-Tricyclo[3.2.1.$0^{2,4}$]oct-6-ene
  cycloaddition reactions, 1187
Tricyclopentanoids
  angularly-fused
    synthesis *via* photocycloaddition, 662
Tricyclo[6.4.2.0.$2^{3,6}$]tetradeca-1(8),4,13-triene
  isomerization
    *via* retro Diels–Alder reactions, 585
Tricyclo[5.2.2.$0^{2,6}$]undecadiones
  synthesis
    *via* photoisomerization, 233
Tricyclo[6.3.0.$0^{1,5}$]undecane
  synthesis
    *via* Pauson–Khand reaction, 1057
Tricyclo[6.3.0.$0^{2,6}$]undecanes
  synthesis
    *via* photocycloaddition, 664
*trans*-Tricyclo[5.4.0.$0^{4,6}$]undec-2-ene
  synthesis
    *via* thermal rearrangement, 716

# Preface

The emergence of organic chemistry as a scientific discipline heralded a new era in human development. Applications of organic chemistry contributed significantly to satisfying the basic needs for food, clothing and shelter. While expanding our ability to cope with our basic needs remained an important goal, we could, for the first time, worry about the quality of life. Indeed, there appears to be an excellent correlation between investment in research and applications of organic chemistry and the standard of living. Such advances arise from the creation of compounds and materials. Continuation of these contributions requires a vigorous effort in research and development, for which information such as that provided by the *Comprehensive* series of Pergamon Press is a valuable resource.

Since the publication in 1979 of *Comprehensive Organic Chemistry*, it has become an important first source of information. However, considering the pace of advancements and the ever-shrinking timeframe in which initial discoveries are rapidly assimilated into the basic fabric of the science, it is clear that a new treatment is needed. It was tempting simply to update a series that had been so successful. However, this new series took a totally different approach. In deciding to embark upon *Comprehensive Organic Synthesis*, the Editors and Publisher recognized that synthesis stands at the heart of organic chemistry.

The construction of molecules and molecular systems transcends many fields of science. Needs in electronics, agriculture, medicine and textiles, to name but a few, provide a powerful driving force for more effective ways to make known materials and for routes to new materials. Physical and theoretical studies, extrapolations from current knowledge, and serendipity all help to identify the direction in which research should be moving. All of these forces help the synthetic chemist in translating vague notions to specific structures, in executing complex multistep sequences, and in seeking new knowledge to develop new reactions and reagents. The increasing degree of sophistication of the types of problems that need to be addressed require increasingly complex molecular architecture to target better the function of the resulting substances. The ability to make such substances available depends upon the sharpening of our sculptors' tools: the reactions and reagents of synthesis.

The Volume Editors have spent great time and effort in considering the format of the work. The intention is to focus on transformations in the way that synthetic chemists think about their problems. In terms of organic molecules, the work divides into the formation of carbon–carbon bonds, the introduction of heteroatoms, and heteroatom interconversions. Thus, Volumes 1–5 focus mainly on carbon–carbon bond formation, but also include many aspects of the introduction of heteroatoms. Volumes 6–8 focus on interconversion of heteroatoms, but also deal with exchange of carbon–carbon bonds for carbon–heteroatom bonds.

The Editors recognize that the assignment of subjects to any particular volume may be arbitrary in part. For example, reactions of enolates can be considered to be additions to C—C $\pi$-bonds. However, the vastness of the field leads it to be subdivided into components based upon the nature of the bond-forming process. Some subjects will undoubtedly appear in more than one place.

In attacking a synthetic target, the critical question about the suitability of any method involves selectivity: chemo-, regio-, diastereo- and enantio-selectivity. Both from an educational point-of-view for the reader who wants to learn about a new field, and an experimental viewpoint for the practitioner who seeks a reference source for practical information, an organization of the chapters along the theme of selectivity becomes most informative.

The Editors believe this organization will help emphasize the common threads that underlie many seemingly disparate areas of organic chemistry. The relationships among various transformations becomes clearer and the applicability of transformations across a large number of compound classes becomes apparent. Thus, it is intended that an integration of many specialized areas such as terpenoid, heterocyclic, carbohydrate, nucleic acid chemistry, *etc.* within the more general transformation class will provide an impetus to the consideration of methods to solve problems outside the traditional ones for any specialist.

In general, presentation of topics concentrates on work of the last decade. Reference to earlier work, as necessary and relevant, is made by citing key reviews. All topics in organic synthesis cannot be treated with equal depth within the constraints of any single series. Decisions as to which aspects of a

topic require greater depth are guided by the topics covered in other recent *Comprehensive* series. This new treatise focuses on being comprehensive in the context of synthetically useful concepts.

The Editors and Publisher believe that *Comprehensive Organic Synthesis* will serve all those who must face the problem of preparing organic compounds. We intend it to be an essential reference work for the experienced practitioner who seeks information to solve a particular problem. At the same time, we must also serve the chemist whose major interest lies outside organic synthesis and therefore is only an occasional practitioner. In addition, the series has an educational role. We hope to instruct experienced investigators who want to learn the essential facts and concepts of an area new to them. We also hope to teach the novice student by providing an authoritative account of an area and by conveying the excitement of the field.

The need for this series was evident from the enthusiastic response from the scientific community in the most meaningful way — their willingness to devote their time to the task. I am deeply indebted to an exceptional board of editors, beginning with my deputy editor-in-chief Ian Fleming, and extending to the entire board — Clayton H. Heathcock, Ryoji Noyori, Steven V. Ley, Leo A. Paquette, Gerald Pattenden, Martin F. Semmelhack, Stuart L. Schreiber and Ekkehard Winterfeldt.

The substance of the work was created by over 250 authors from 15 countries, illustrating the truly international nature of the effort. I thank each and every one for the magnificent effort put forth. Finally, such a work is impossible without a publisher. The continuing commitment of Pergamon Press to serve the scientific community by providing this *Comprehensive* series is commendable. Specific credit goes to Colin Drayton for the critical role he played in allowing us to realize this work and also to Helen McPherson for guiding it through the publishing maze.

A work of this kind, which obviously summarizes accomplishments, may engender in some the feeling that there is little more to achieve. Quite the opposite is the case. In looking back and seeing how far we have come, it becomes only more obvious how very much more we have yet to achieve. The vastness of the problems and opportunities ensures that research in organic synthesis will be vibrant for a very long time to come.

BARRY M. TROST

## 1.1.1 INTRODUCTION

Alcohols can be obtained from many other classes of compounds such as alkyl halides, amines, alkenes, epoxides and carbonyl compounds. The addition of nucleophiles to carbonyl compounds is a versatile and convenient method for the the preparation of alcohols. Regioselective oxirane ring opening of epoxides by nucleophiles is another important route for the synthesis of alcohols. However, stereospecific oxirane ring formation is prerequisite to the use of epoxides in organic synthesis. The chemistry of epoxides has been extensively studied in this decade and the development of the diastereoselective oxidations of alkenic alcohols makes epoxy alcohols with definite configurations readily available. Recently developed asymmetric epoxidation of prochiral allylic alcohols allows the enantioselective synthesis of 2,3-epoxy alcohols.

For reason of space, emphasis will be placed on the reaction of functionalized epoxides with carbon nucleophiles. However, isomerization of epoxides and intramolecular oxirane ring opening leading to cyclic compounds could not be included. In order to avoid overlap with other articles in this series, reductive cleavage of epoxides is not discussed. Some 1,2-rearrangement reactions leading to alcohols are described because the reactions are apparently useful for the preparation of alcohols with high stereoselectivity. Substitution at the carbon atom adjacent to oxygen, which is an important method for the conversion of ethers, could not be considered. The conventional but still important classes of displacement reactions such as those involving alkyl halides or amines are discussed briefly. Readers are referred to excellent reviews and monographs.[1-3]

## 1.1.2 PREPARATION OF ALCOHOLS

### 1.1.2.1 Substitution of Alkyl Halides

Although the hydrolysis of alkyl halides to alcohols has been extensively investigated,[1] an alternative two-step sequence involving substitution with carboxylate ion is more practical for the preparation of alcohols.[4] Activation of the carboxylate anion prepared by the reaction of the acid with a base can be achieved:[5] (i) by use of a polar aprotic solvent; and (ii) by use of aprotic apolar solvents under phase transfer catalysis, polymer conditions, or with crown ethers.

The second-order alkylation rates of carboxylate salts are influenced by the nature of the cation, solvent and the alkyl halides. In general, carboxylate anions with soft (large) counterions are more reactive than those with hard counterions because of higher charge separation in the former.[6] Thus, the anticipated order of increasing reactivity $Li^+(1) < Na^+(1.1) < K^+(1.5) < Cs^+(2)$ was observed in the reaction of 2-methyl-2-propylpentanoate with 1-iodopentane at 60 °C in HMPA–EtOH (1:1 v/v).[6]

Rapid and nearly complete alkylation of carboxylate salts with reactive organic halides has been demonstrated in nonpolar and polar solvents. With less reactive alkyl halides, the use of dipolar aprotic solvents for alkylation has been marginally successful.[6] The rate of alkylation of potassium 2-methyl-2-propylpentanoate with 1-chlorohexane in four dipolar aprotic solvents at 60 °C decreased in the order HMPA > *N*-methylpyrrolidone > DMSO > DMF.[6]

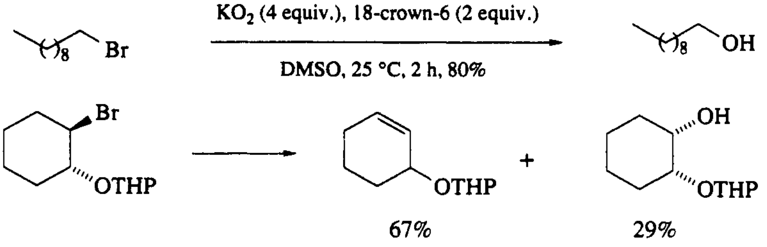
The order of reactivity of the halogen in simple alkyl halides in $S_N2$ reactions is I > Br > Cl. The relative rates of the alkylation of potassium 2-methyl-2-propylpentanoate with 1-iodopentane, 1-bromopentane and 1-chlorohexane in HMPA at 60 °C are reported to be 587, 35 and 1.[6]

Elucidation of rates with variation in cation, solvent and halide ion indicates that the combination of alkyl iodides and cesium salts in HMPA offers the optimum alkylation conditions for preparative use.[6] The reactions of cesium carboxylates with alkyl halides and sulfonates will be discussed in Section 1.1.2.5 in connection with inversion processes.

One of the crucial side reactions in the displacement reactions of alkyl halides is elimination, which can generally be neglected in the reaction of primary alkyl halides. On the other hand, a considerable amount of alkene invariably forms in the reaction of secondary alkyl halides. This undesirable side reaction can be minimized by the use of cesium carboxylates.[7]

The reaction of potassium carboxylates with alkyl halides without the use of a solvent in the presence of catalytic amounts of a tetraalkylammonium salt proceeds smoothly to give the corresponding esters in good to excellent yields, except for cyclohexyl bromide where elimination mainly takes place.[5] Alkylation of *o*- and *p*-hydroxybenzoic acid selectively takes place at the $CO_2K$ group.[5a]

A more direct procedure for the displacement step is the use of a very powerful nucleophilic superoxide radical ion where an alkyl halide or sulfonate is directly converted into the corresponding alcohol (Scheme 1).[8] Elimination is an important side reaction in certain cases.[8a]



Scheme 1

On treatment with suitable oxidizing agents, alkyl iodides are transformed into products of either elimination or nucleophilic substitution, depending on the initial structure and the reaction conditions.[9] Effective oxidants include $Cl_2$, $Br_2$, $HNO_3$, $N_2O_5$, $AcONO_2$, $NOBF_4$, $NO_2BF_4$, $K_2Cr_2O_7$, $KMnO_4$, $Cl_2O_7$, $ClOClO_3$, $Cl_2O$, $(FSO_2O)_2$, $I(CO_2CF_3)_3$, $PhI(CO_2CF_3)_2$ and MCPBA (Scheme 2). The intermediacy of hypervalent organoiodides has been proposed; groups containing hypervalent iodine are good leaving groups. For example, otherwise unreactive 1-iodonorbornane can be converted into the corresponding bromide.[9]

Allylic iodides with excess amounts of peroxy acids in a two-phase system in the presence of an inorganic base give the corresponding rearranged allylic alcohols in good yields (Scheme 3).[10] It has been demonstrated that the reaction proceeds under milder conditions than the Mislow–Evans reaction.[10]

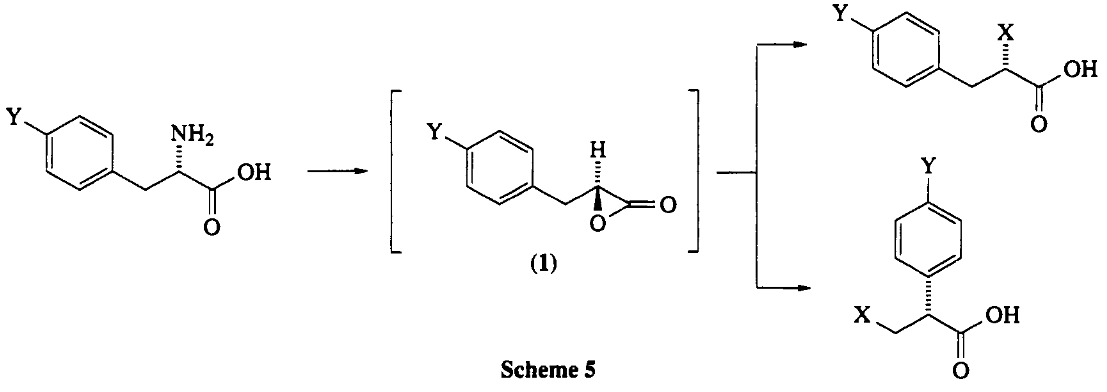
### 1.1.2.2 Deamination of Amines *via* Diazonium Salts

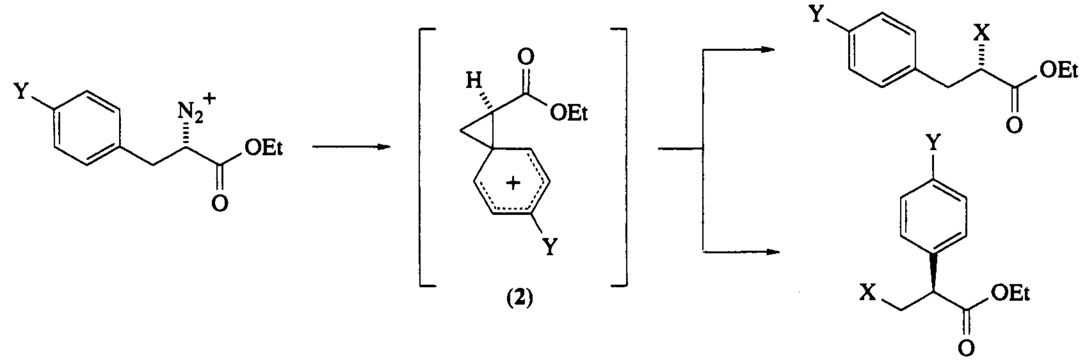
Treatment of a primary aliphatic amine with nitrous acid or its equivalent produces a diazonium ion which results in the formation of a variety of products through solvent displacement, elimination and solvolysis with 1,2-shift and concurrent elimination of nitrogen.[12] The stereochemistry of the deamination–substitution reaction of various secondary amines was investigated as early as 1950, when an $S_N1$-type displacement was suggested.[13] Thus, the process can hardly be utilized for the preparation of alcohols except in cases where additional factors controlling the reaction course exist. Deamination–substitution of α-amino acids can be utilized for the preparation of chiral alcohols.

The reaction of optically active α-amino acids with nitrous acid or nitrosyl chloride gives α-hydroxy or α-halo acids with retention of configuration due to the neighboring carboxylate participation.[14–17] Examination of the reaction of phenylalanine and its *para*-substituted derivatives revealed that the product distribution and outcome of the stereochemistry depend on both the solvent used and the substituent on the aromatic ring. The results may be rationalized by assuming the intermediacy of an unstable lactone (**1**). When a solvent of high nucleophilicity is used, it attacks the α-carbon of (**1**) from the backside of the oxygen to give the corresponding substituted product with net retention of configuration. When the reaction is carried out in a solvent of low nucleophilicity, the aryl group migration takes place prior to intermolecular displacement to afford the migration product (Scheme 5).[18]



**Scheme 5**

Contrary to the case of free α-amino acids, deamination–substitution of esters of α-amino acids generally proceeds with racemization with excess inversion about the α-carbon atom.[13,18] However, reaction of the ethyl ester of phenylalanine and its derivatives with sodium nitrite in trifluoroacetic acid affords substitution products with retention of configuration and migration products with inversion of configuration. This result may be explained by assuming initial formation of the phenonium intermediate (**2**; Scheme 6).[18]



**Scheme 6**

### 1.1.2.3 Oxirane Ring Opening by Carbon Nucleophiles

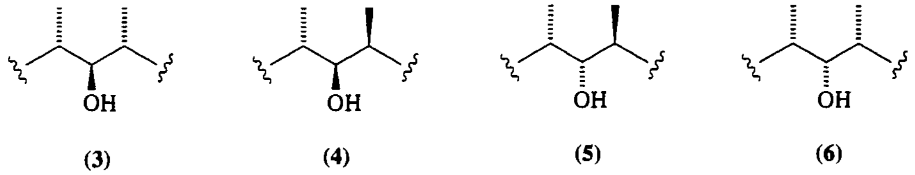
#### *1.1.2.3.1 Reaction of epoxides with organometallic reagents*

The reaction of epoxides with carbon nucleophiles generates new carbon–carbon σ-bonds, and this reaction can be utilized as a versatile procedure for the preparation of a variety of alcohols, provided that the ring opening takes place in a regioselective manner. This section deals with the reactions of organometallic reagents with 2,3-epoxy alcohols and conjugated epoxides, *i.e.* where the oxirane ring is directly bonded to a π-electron system. The behavior of conjugated epoxides toward nucleophiles can be rationalized in terms of the principle of 'hard and soft acids and bases (HSAB)'.[19]

The reactions of epoxides with organometallic reagents are sometimes curtailed owing to competing reactions arising from the Lewis acidity or basicity of the organometallics used.[20] The hardness of the organometallic reagent (RLi > RMgX > RCu or $R_2CuLi$) is directly related to the metal atom.[21] Of carbon nucleophiles, organocuprates are the reagents of choice, while Grignard reagents sometimes result in concomitant formation of side products arising from the substitution by halide ion.[19a,20] Higher order mixed organocuprates of the general formula $R_2Cu(CN)Li_2$ are superior to $R_2CuLi$.[22] The cyanocopper reagents are considered to be softer than the cuprate and simple copper reagents.[19c] The reactions using organoaluminum reagents are interesting alternatives to those using organocopper reagents where complementary regioselectivity is generally observed.[23] It is noteworthy that the addition of $BF_3{\cdot}Et_2O$ causes enhancement of reactivity.[23e]

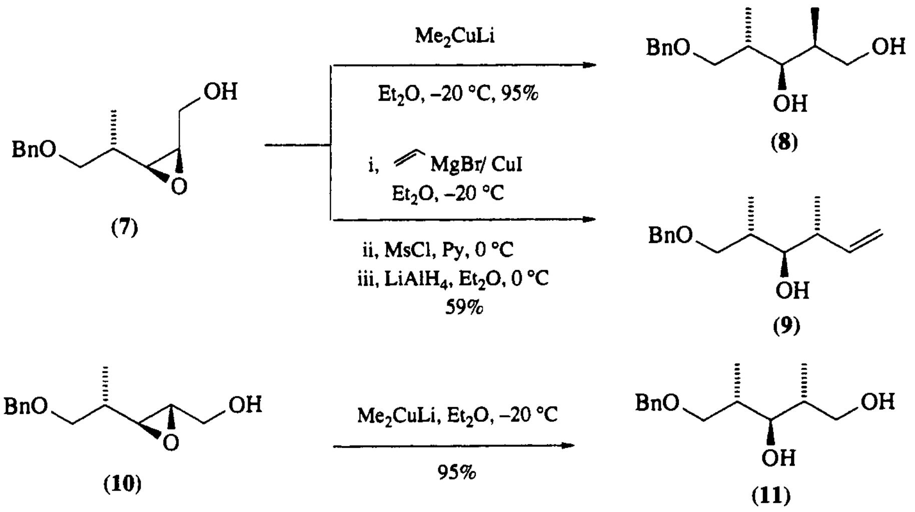
### *1.1.2.3.2 2,3-Epoxy alcohols*

The partial structural unit with definite configuration at three consecutive chiral centers, (**3**), (**4**), (**5**) or (**6**), is often found in natural products (Scheme 7).



Scheme 7

Kishi and coworkers have studied the ring opening of 2,3-epoxy alcohols having different stereochemistry.[24] (*Z*)-Epoxy alcohol (**7**) reacted with $Me_2CuLi$ to give exclusively (**8**). Alternatively, the reaction of (**7**) with vinylcuprate followed by deoxygenation afforded (**9**). The reaction of (**10**) with $Me_2CuLi$ gave (**11**; Scheme 8).[24]



Scheme 8

The reaction of (**12**) with $Me_2CuLi$ also takes place at C-2 to give (**13**) without contamination of the regioisomeric 1,2-diol.[25] In the reaction of tritylated 3,4-epoxy alcohol (**14**; Scheme 9) with homoallylcuprate (**15**), addition of $BF_3{\cdot}Et_2O$ was required for the initiation of the reaction producing (**16**) along with a small amount of (**17**).[26]

The reaction of (*E*)-(**18**) with $Me_2CuCNLi_2$ shows a moderate level of regioselectivity, giving a 6:1 ratio of 1,3-diol (**19a**) and regioisomeric 1,2-diol (**20**).[27a] The corresponding (*Z*)-epoxide (*Z*)-(**18**) reacts with $Me_2CuLi$ to give the 1,3-diol (**19b**) as the sole product.[27b] The reaction of the less-hindered epoxide (**21**) or (**22**) with $Me_2CuLi$ does not show any regioselectivity, affording a mixture of isomeric diols in a ratio of 1:1 (Scheme 10).[24a,27c] These results suggest that the regiochemical preference observed in the reactions of epoxy alcohols appears to be steric in origin.[27d]

On the other hand, the reaction of (**23a**) with $Me_2CuLi$ yields a 55:45 mixture of 1,2- and 1,3-diols. The reaction of the TBDMS derivative (**23b**) with $Me_2CuLi$ under identical conditions results in the formation of (**24**) with about 20:1 regioselectivity. In this case, the regioselectivity observed has been attributed to complexation of the nucleophile with the substrate.[28]

C-3 selectivity has been attained by the use of 2,3-epoxy alcohols having a bulky protective group. Thus, (**25**) reacts with alkenylmagnesium bromide (**26**) in the presence of a catalytic amount of CuI to

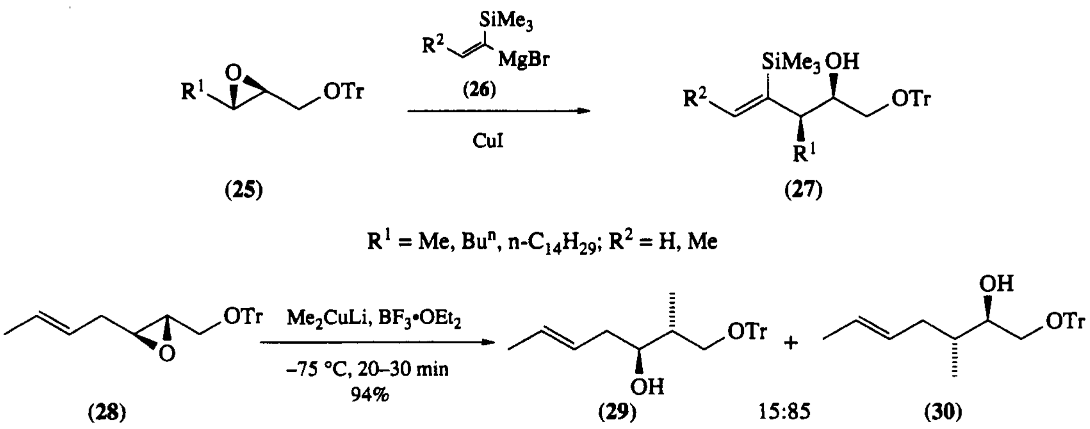
give (**27**) as the sole product.[29a] Contrary to the case of (**25**), the reaction of (**28**) with a variety of organocuprates gives (**29**) and (**30**) in ratios ranging from 1:1 to 1.5:1, favoring the 1,3-diol derivative (**29**). However, when the reaction was carried out with 2 equiv. each of Me$_2$CuLi and BF$_3$·Et$_2$O, (**29**) and (**30**) were formed in a ratio of 15:85 (Scheme 12).[29b]



**Scheme 12**

C-3 attack predominantly takes place in the reaction of 2,3-epoxy alcohols with organoaluminum compounds such as Me$_3$Al, PhC≡CAlEt$_2$, Me$_3$SiC≡CAlEt$_2$, Bu$^i_2$AlH and Bu$^i_3$Al.[30] The yield and stereochemical outcome depend on the substrates and organoaluminum reagents used.[30c]

The following examples illustrate the complementary regioselectivities exhibited in the reactions using Me$_2$CuLi and Me$_3$Al (Scheme 13).[30a,30b] One problem which remains to be solved, however, is the proclivity of alkylaluminum reagents such as Et$_3$Al to serve as hydride donors.[30a]

| (*Z*)-epoxide | 87 | 95:5 |
| (*E*)-epoxide | 85 | 99:1 |

**Scheme 13**

Epoxide (**31**) reacts with 2 equiv. of lithium acetylide–ethylenediamine complex at the C-3 position.[31] Terminal epoxide (**32**) reacts smoothly with the lithium alkynide (**33**) to give a 1,2-diol in good yield.[32] Alkynylboranes (**34**) have been demonstrated to be useful for alkynylation of epoxides (Scheme 14).[33]

The reactions of 2,3-epoxy alcohols with organometallic reagents are influenced by various factors which include not only the solvent and the structure of the reactants but also the gegen cation of the oxyanion of the epoxy alcohol. Sulfone-stabilized allyllithium (**35b**) reacts sluggishly with lithium alkoxide (**36a**) in THF–HMPA to give the coupled product (**37a**) in 9% yield with 90% recovery of (**35a**). Under identical conditions, however, the magnesium epoxide (**36b**) gave (**37a**) in 70% yield as an 8:1 mixture of diastereomers. In contrast, (**36a**) reacts negligibly with (**35b**) in THF. Furthermore, the TMS ether (**36c**) and the ethoxyethyl (EE) ether (**36d**) give no coupling product at all with (**35b**). Although the thiophenyl-stabilized allyllithium (**35c**) is more reactive than (**35b**), the corresponding coupling product (**37b**) is obtained as a 1:1 mixture of diastereomers (Scheme 15).[34]

**Scheme 15**

The reaction of (*Z*)-3-hydroxycyclohexene oxide (**38a**) with $Me_2CuLi$ gave 1,2-diol (**39a**) in preference to 1,3-diol (**40a**), while the (*E*)-isomer (**41a**) showed the reversed regioselectivity. The corresponding methyl ethers (**38b**) and (**41b**) showed even lower regioselectivity than the unprotected substrates.[35a] These results suggest that the regioselectivity is controlled by various factors, including conformational effects.

Danishefsky and coworkers have studied the ring opening reactions of a series of (*Z*)- and (*E*)-epoxides, (**38a**), (**38c**), (**41a**) and (**41c**), with $^-CH_2CO_2^-$ and with $Et_2AlC{\equiv}COEt$ and have demonstrated that the reaction course in the alane opening depends largely on the stereochemical relationship between the oxy function and the epoxide, and only to an insignificant extent on whether the oxygen is initially in the form of a hydroxy group or a trimethylsilyl ether. On the other hand, in the dianion case, the nature of the oxygen, rather than its stereochemical relationship with the epoxide, is decisive for the regioselectivity of the ring opening.[35b]

Regioselectivity is markedly enhanced in conformationally more biased systems such as carbohydrates and fused bicyclic compounds. Some examples are shown in Scheme 17.[36–38]

In view of the large number of naturally occurring polyols having definite configuration, a variety of methodologies to construct such systems by utilizing the reactivity of epoxides have been reported.[39]

### 1.1.2.3.3 Vinyl epoxides

The reaction of 3,4-epoxy-1-butene (**44**) with Grignard reagents affords a mixture of products resulting from direct attack on the oxirane ring ($S_N2$) and on the double bond ($S_N2'$). The product distribution depends on the nature of the Grignard reagents. Alkyllithiums are favored for the direct attack on the oxirane carbon (C-3 attack), while lithium dialkylcuprates give the $S_N2'$ displacement products (C-1 attack) with high regioselectivity (Scheme 18, Table 1).[20b,22,40]

The regioselectivity of the reaction of organo-yttrium and -lanthanoid reagents with (**44**) is complementary (C-3 attack) to that obtained with organocuprates (Table 1).[40b]

In contrast to the reactions of acyclic substrates, 3,4-epoxycyclohexene (**48**) reacts with Me$_2$CuLi to give both $S_N2$ and $S_N2'$ displacement products (**49**) and (**50**).[41] By the use of MeCuCNLi, however, (**48**) gives (**49**) in 95% yield (100% *trans*).[42a] The resulting product of general formula (**51**) can be converted into an epoxy enol ether (**52**) which again undergoes anti-$S_N2'$ reaction with MeCuCNLi to produce (**53**) in essentially quantitative yield (Scheme 19).[42b,43]

The reaction has been extended to 1,4-chirality transfer. For instance, epoxide (**54**) reacts with lithium isohexylcyanocuprate to afford isomerically pure (**55**; Scheme 20).[42c] This strategy has been applied to the total synthesis of prostaglandins.[42d]

In general, $S_N2'$ displacement on cyclic vinyl epoxides by organocopper reagents has been found to proceed with inversion (*anti* pathway). However, acyclic vinyl epoxides can react *via* either *s-cis* or

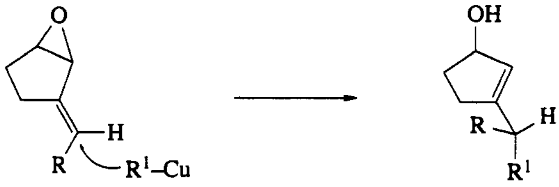
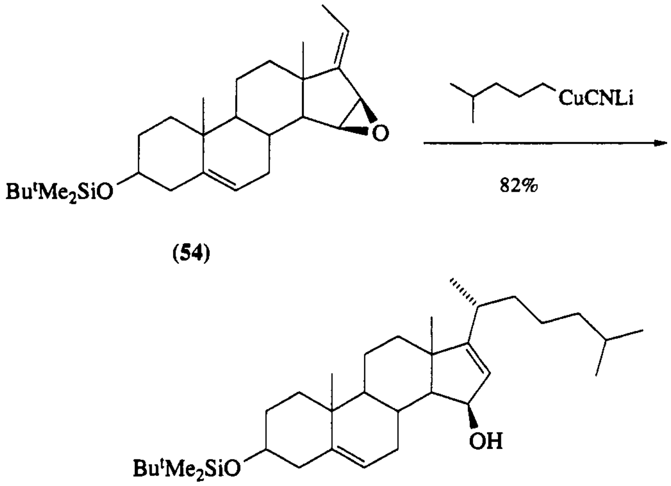
*s- trans* conformers and thus yield mixtures of (*E*)- and (*Z*)-products of $S_N2'$ reaction.[44] Marshall and coworkers have studied the reactions of (*E*)- and (*Z*)-vinyl epoxides, (*E*)-(**56**) and (*Z*)-(**56**), with methylcuprates where not only $S_N2'$ displacement products (*E*)-(**57**) and (*Z*)-(**57**) but also $S_N2$ displacement





**(54)**

**(55)**

**Scheme 20**

products (*E*)-(**58**) and (*Z*)-(**58**) are formed, and diene (**59**) as well (Scheme 21, Table 2).[44] The more-substituted systems, (*E*)- and (*Z*)-(**60**), and (*E*)- and (*Z*)-(**61**), yield only $S_N2'$ displacement products. In all the cases examined ($Me_2CuLi$, $THF/Et_2O$ 4:1, 0 °C and MeCuCNLi, $Et_2O$, 0 °C), *anti* attack is more favorable than *syn* attack.[44]

On treatment with a palladium(0) catalyst, vinyl epoxides undergo facile unimolecular rearrangement to give dienols or enones depending on the substitution pattern of the substrate.[45] In the presence of an active methylene compound in the reaction system, however, a single alkylation product is formed.[46] Cyclic and acyclic vinyl epoxides participate equally well. The reaction proceeds with clean alkylation from the same face as the oxygen of the epoxide, and proceeds with allyl inversion (Scheme 22).[46]

### *1.1.2.3.4 2,3-Epoxy acids*

The reactions of organometallics with 3-substituted glycidic esters proceed through C-2 or C-3 attack depending on the nature of the reagent. With organocuprates, preferential C-2 attack generally takes place.[47] Thus, the ring opening reactions of methyl 2,3-epoxycarboxylates (**62a**) to (**62d**) with organocuprates proceed with perfect regio- and stereo-control to give the corresponding 3-hydroxycarboxylates (**63**) in around 60% isolated yields with >99% inversion at C-2.[48] However, 2,3-epoxy esters having α-branched substituents at the C-3 position (**62e**, **62f**) are inert and are recovered unchanged (Scheme 23).[48]

On the other hand, terminal epoxy esters react with cuprates $R_2CuM$ (M = Li, Mg) at the C-3 position to afford exclusively 2-hydroxy esters (Scheme 23).[47a]

C-3 attack on nonterminal 2,3-epoxy esters takes place when organoaluminum reagents are used instead of cuprates (Scheme 24).[49]

The reactions of (*E*)-2,3-epoxy acids (*E*)-(**64**) with organocopper reagents afford the products of attack at C-2 (**65**) in preference to those at C-3 (**66**), while (*Z*)-isomer (*Z*)-(**64**) undergoes C-3 attack to give (**68**) as the main products (Scheme 25).[50]

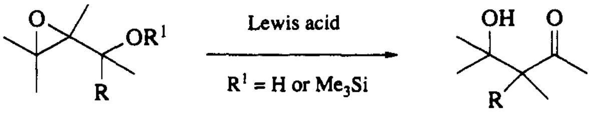
### 1.1.2.4 Rearrangement Reactions Leading to Alcohols

#### *1.1.2.4.1 Sigmatropic rearrangement*

[2,3] Sigmatropic rearrangements such as the Wittig rearrangement and the rearrangements of sulfoxides and selenoxides are considered as intramolecular $S_N2'$ reactions producing unsaturated alcohols and have long received widespread interest because of their synthetic importance. The reactions involving 1,2-shift can, in a sense, also be considered as intramolecular displacements and generally take place with high stereospecificity with respect to the migrating group and the migration terminus. This section briefly deals with some 1,2-rearrangement processes which can be utilized in the preparation of chiral alcohols. Since [2,3] sigmatropic rearrangements and organoboron chemistry have been surveyed in excellent review articles and monographs,[51] these subjects are not covered in this section.

#### *1.1.2.4.2 Epoxy silyl ether rearrangement*

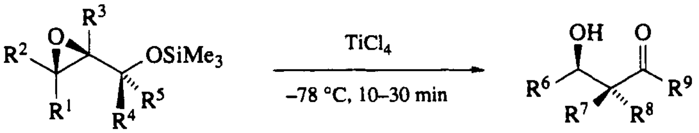
The Lewis acid mediated rearrangement of epoxy silyl ether (**69**) affords the corresponding β-hydroxycarbonyl compound (**70**; Scheme 26).[52]



**(69)** **(70)**

**Scheme 26**

In the reaction of α,α,β-trialkyl derivative (**71a**), facile migration of the alkyl group is observed, whereas the aryl group migrates preferentially from the alkyl aryl derivative (**71b**; Scheme 27, Table 3).[52]



**(71a)–(71g)** **(72)–(77)**

**Scheme 27**

In the case of β-monosubstituted derivatives (**71c**) to (**71g**), only aryl and alkenyl groups participate in the selective 1,2-rearrangement, reflecting the low migratory aptitude of the alkyl group. The rearrangement is highly stereoselective with respect to the geometry of the epoxide moiety but not to the configuration of the alkoxy α-carbon. Thus, both *erythro–trans* isomer (**71c**) and *threo–trans* isomer (**71d**) give the same *threo*-aldol (**74**) as the sole isolable product, while *threo–cis* isomer (**71e**) exclusively gives *erythro*-aldol (**75**). Epoxides (**71f**) and (**71g**) give (**76**) and (**77**), respectively.[52] These results can be interpreted as the rigorous *anti* migration of the phenyl and alkenyl groups with complete retention of the alkene geometry.[52,53]

Concerning Lewis acids, a catalytic amount of $Me_3SiI$ or $Me_3SiOTf$, as well as a stoichiometric amount of $TiClO_4$ or $BF_3{\cdot}Et_2O$, is effective. The favorable choice of Lewis acids with respect to the substitution pattern of the substrates has been reported.[54] This methodology has been successfully utilized in the total synthesis of natural products which include avenaciolide and mycinolide IV.[54,55]

#### *1.1.2.4.3 Criegee rearrangement*

The acylations of α-alkoxy hydroperoxides such as (**79**) furnish peroxy esters that are related to the intermediate produced in the Baeyer–Villiger reaction.[56–58] The peroxy ester undergoes the Criegee rearrangement to a dioxonium ion which in turn is converted into an ester. Thus, ozonolysis of (+)-(*E*)-dihydrocarvone (**78**) affords a 1:1 mixture of diastereomers (**79**). Acetylation and rearrangement

**Table 3** Rearrangement of (71) (Scheme 27)[52]

provides (**81a**) and (**81b**) in 60% and 20% yields, respectively, after aqueous work-up.[56] The intermediate peroxy acetate (**80**) can be isolated (84% yield) and purified (Scheme 28).[56] Similarly, lactone (**82**) is successfully converted into (**84**), which is differentially functionalized at the termini of the growing chain, *i.e.* primary hydroxy group and double bond.[58]

### *1.1.2.4.4 Oxidative cleavage of silicon–carbon bonds leading to alcohols*

Certain functionalized silyl groups bonded to $sp^3$- or $sp^2$-carbon atoms (**85**) are readily converted into hydroxy groups on treatment with peroxy acids or $H_2O_2$ (Scheme 29).[59–61]

$$\underset{(\mathbf{85})}{R_nSiF_{4-n}} \quad + \quad \text{MCPBA} \longrightarrow n\text{ROH}$$

**Scheme 29**

The oxidative cleavage reactions are considered to proceed through the intramolecular migration of the organic group to the oxygen in extracoordinate silicon intermediates (Scheme 30).[59] Typical oxidation conditions and silyl groups amenable to conversion to OH groups are summarized in the literature.[59]

When organosilicon compounds of general formula $PhMe_2Si—R$, $(CH_2{=}CHCH_2)Me_2Si—R$ and $(RMe_2Si)_2O$ are used, the Ph—Si, $CH_2$—Si or SiO—Si bond must first be cleaved by fluoride ion to give fluorosilanes which subsequently react with peroxy acids or $H_2O_2$. Recently, the use of $Br_2$–AcOOH or $Hg(OAc)_2$–AcOOH systems has been reported to be effective for the conversion of $PhMe_2Si—R$ into the corresponding alcohols, allowing the two-step sequence to be carried out in one operation (Scheme 32).[62a] The $PhMe_2Si$ group has recently been demonstrated to be superior to the $(Pr^iO)Me_2Si$ group in carbohydrate chemistry.[62b]

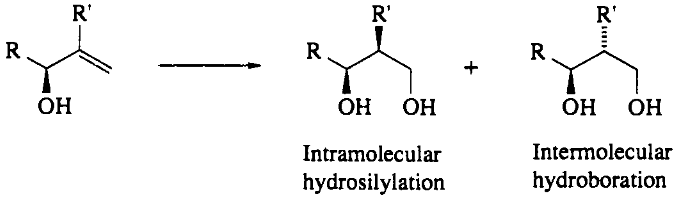
Scheme 32

A one-pot synthesis of anti-Markovnikoff alcohols from terminal alkenes has been achieved by hydrosilylation (catalyst: $H_2PtCl_4$, $[RhCl(PPh_3)_3]$) with alkoxysilanes and subsequent oxidation.[59,63] Although hydrosilylation of internal alkenes is difficult, intramolecular hydrosilylation of allylic and homoallylic alcohols proceeds smoothly with high regio- and stereo-selectivities.[63] In view of the high regioselectivity and the wide range of functional group compatibility, the present method may be a useful alternative to the hydroboration–oxidation process. It is noteworthy that the 1,3-diols formed by intramolecular hydrosilylation–oxidation of allylic and homoallylic alcohols have structures which are complementary to those obtained by the intermolecular hydroboration–oxidation reaction (Scheme 33).[59a,63a] Approaches to construct 1,3-diol skeletons have been demonstrated.[59,63]



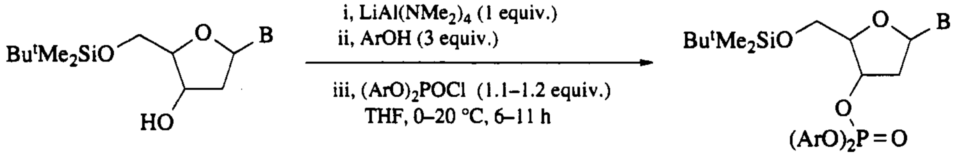
Scheme 33

## 1.1.2.5 Inversion of Alcohols

### 1.1.2.5.1 *Activation of hydroxy groups*

Alcohols are available in a variety of cyclic and acyclic forms, and, as such, have been utilized as versatile starting materials for the construction of carbon compounds including natural products with many centers of chirality. In order to functionalize and manipulate the hydroxy group in alcohols by a displacement process, activation of the hydroxy group is an important step which involves: (i) activation of the O—H bond to enhance the nucleophilicity of the oxygen; or (ii) activation of the R—O bond to convert the alcohol into a reactive alkylating reagent.

Conversion of alcohols into metal alkoxides is a common procedure for the enhancement of nucleophilicity in which the nature of the metal cation affects strongly the reactivity of the alkoxide.[64] Noyori and coworkers have demonstrated that metals having greater affinity to oxygen than to nitrogen allow selective activation of the hydroxy group of $NH_2$-unblocked nucleosides.[65] Thus, lithium alkoxytriaryloxyaluminates $LiAl(OAr)_3$—OR (R = nucleoside residues) react with diaryl phosphorochloridates to give the corresponding nucleotides in 69–88% yields with little (<1%) or no formation of *N*-phosphorylated products (Scheme 34).



Scheme 34

Trialkyltin alkoxides (**86**) and dialkylstannylene[5] (**87**) have recently attracted attention because a tin atom attached to an oxygen atom enhances the nucleophilicity of the latter without increasing its basicity.[64] The synthetic applications of tin alkoxides manifest most remarkably in the case of polyols. For example, 1,2,6-hexanetriol was first stannylated with 1 equiv. of $(Bu_3Sn)_2O$, followed by treatment with benzoyl chloride giving (**88**) in 67% yield. Intermediacy of the tributyltin ether (**89**) was proposed for the regioselective benzoylation (Scheme 35).[66a]

Benzoylation of 1,2-diol (**90**) by the conventional method (BzCl, Py) and subsequent silylation affords primary ester (**92**) in preference to the secondary ester (**93**) in a ratio of 96:4 (81% yield). A dramatic reversal of chemoselectivity is observed when (**90**) is first converted into dioxastannolane (**91**) followed by treatment with benzoyl chloride and work-up, giving (**92**) and (**93**) in a ratio of 5:95 (Scheme 36).[66b]

Another type of activation of the hydroxy group of alcohols involves the introduction of functional groups in order to facilitate the carbon–oxygen bond cleavage in the subsequent nucleophilic displacement reactions, *i.e.* conversion of an alcohol into a reactive alkylating reagent.

Sulfonation of alcohols is a most common approach to this end. The reactivity of sulfonates is strongly influenced by the solvent used. The kinetic study of the nucleophilic substitution of a series of *n*-octyl derivatives $C_8H_{17}X$ (X = Cl, Br, I, OTs and OMs) with $N_3^-$ in different solvents (MeOH, DMSO, PhCl and cyclohexane) reveals the following nucleofugacity scales: OTs > I > OMs ≥ Br >> in MeOH; I > Br

Triflates are more reactive than mesylates and tosylates.[68] Triflates are generally prepared by the reaction of alcohols with triflic anhydride in the presence of pyridine at low temperature. In the case where concomitant pyridinium salt formation lowers the yield of the desired triflate, more-hindered bases such as (**94**) have been used (Scheme 37).[69]

Nucleophilic openings of cyclic sulfonates which are less hindered, or activated by an adjacent carbonyl group, occur at room temperature in usually less than 30 min. In these reactions, DMF is the solvent of choice. Selective hydrolytic removal of the sulfate group can be achieved under controlled conditions (Scheme 38).[70]

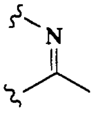
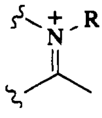
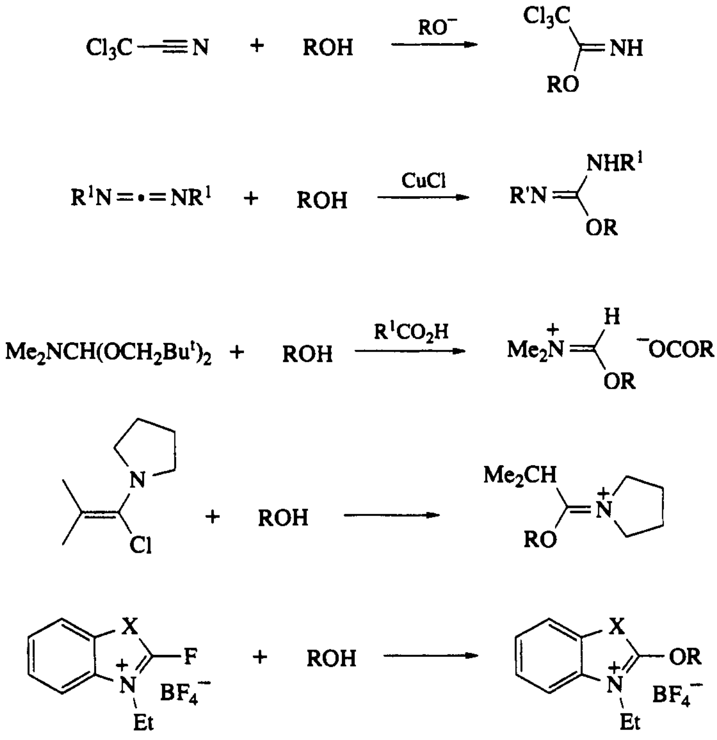
Introduction of partial structure (**95**) or (**96**) into the hydroxy group of an alcohol is also effective for activating the carbon–oxygen bond. Typical reactive imino and imidium ethers are shown in Scheme 39.[71-75]



(**95**)



(**96**)



**Scheme 39**

Alkoxyphosphonium salts (**99**), formed by the reaction of trivalent phosphorus compounds with oxidizing electrophiles (**97**) in the presence of alcohols, have been recognized as versatile and reactive alkylating reagents. Although the mechanism has not yet been fully elucidated, the reaction might involve initial formation of (**98**). Compound (**98**) in turn reacts with an alcohol to give (**99**) which can undergo nucleophilic substitution either with its own counteranion (path a or b) or with other nucleophiles present in the reaction system (path c in Scheme 40). Thus, in order to facilitate the alkylation of external nucleophiles (path c), the choice of (**97**) is crucial for the success of the conversion. The reaction generally proceeds under mild conditions and possesses some valuable features such as regioselectivity; no allylic rearrangement; and inversion of configuration at the secondary carbinol centers. Comprehensive review articles on this process have been published.[76]

π-Allylpalladium complexes formed by the reaction of allyl acetates with palladium(0) compounds react with nucleophiles yielding the allylic alkylation products. In this catalytic process, the allylic position of the allyl alcohols is activated by acetylation.[77] The displacement reactions of sulfonates or alkoxyphosphonium salts generally take place with inversion of configuration. In contrast, the palladium-assisted alkylation proceeds with net retention of configuration (Scheme 41).[77]

### *1.1.2.5.2 Inversion of alcohols*

Although many useful methods to produce chiral alcohols have recently been developed, there is still need of a convenient procedure to invert the configurations of secondary carbinol centers. In principle, the inversion of configuration could be accomplished by initial activation of the R—OH bond of an alcohol and subsequent $S_N2$ displacement using oxyanions. The reaction sequences that can be used in the inversion of configuration are summarized in Scheme 42.

Scheme 42

The reactions of alkyl sulfonates with sodium, potassium or tetraalkylammonium carboxylates generally proceed with inversion of configuration. In the case of *s*-alkyl sulfonates, however, a varied amount of elimination products is invariably formed.[78] Of all metal carboxylates, cesium salts (Scheme 43) have proved vastly superior with respect to reactivity and the suppression of undesirable side reactions.[79]

The addition of 18-crown-6 to the reaction system is effective for suppression of the elimination reaction. Thus, the mesylate of (**100**; Scheme 43) reacts with AcOCs in the presence of 18-crown-6 (0.5 equiv.) in benzene (reflux, 1 h) to afford the inverted acetate (**101**) in 70% yield along with a small amount of elimination product (<5%). Without the crown ether, the elimination product is predominantly formed.[79e]

Nitrate ion can be another effective nucleophile for inversion. It has been demonstrated that, due to the low basicity of the nucleophile, the competing elimination reaction is almost completely suppressed and the resulting nitro esters can be readily converted into alcohols by reductive processes.[80] One serious

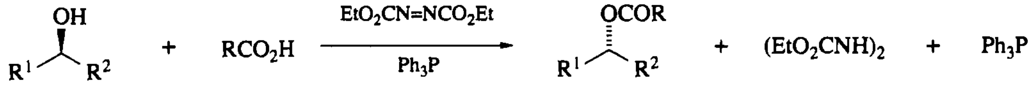
drawback of the procedure is that racemization takes place to some extent under the reaction conditions. However, the racemization can be circumvented by the use of more efficient leaving groups such as the pyridylsulfonyloxy group.[80]

The reactions of alkyl sulfonates with superoxide ion and with nitrite ion directly afford the corresponding inverted alcohols.[8,81] Although displacement by superoxide ion has been successfully utilized in prostaglandin chemistry, elimination again takes place to some extent, depending on the structures of the substrates. In the reaction with nitrite ion, ketone and nitroalkane are also formed. The inversion of cyclopentanol derivatives *via* tosylates has been studied by the use of various methods involving displacement by benzoate, nitrite ion and superoxide ion as well as the diethyl azodicarboxylate (DEAD)–$Ph_3P$ procedure, where varied amounts of elimination products are invariably formed.[81a]

Imino ethers and 2-alkoxybenzthiazolium salts prepared from chiral alcohols react with carboxylic acids to give the esters of the corresponding inverted alcohols (Scheme 39).[71c,72d,73,75a] The reaction of a chiral alcohol with a carboxylic acid, DEAD and $Ph_3P$ affords the ester of the inverted alcohol (Scheme 44).[82] Diisopropyl or dimethyl azodicarboxylate can be used instead of DEAD. Little difference between these reagents has been reported.[83]



**Scheme 44**

Although the DEAD–$Ph_3P$ procedure has been utilized in the inversion of a variety of alcohols, sterically crowded hydroxy groups do not enter into the reaction. In such cases, the sulfonate route can be used. For example, the coupling of free acid (**102a**) with alcohol (**103a**) by the use of DEAD and $Ph_3P$ affords the desired inverted ester (**104a**) in <30% yield, while mesylate (**103b**) reacts with potassium carboxylate (**102b**) (DMF, 75 °C, 18 h) to give (**104b**) in 86% yield (Scheme 45).[84]

The reagent formed by combining $Ph_3P$ with benzoyl peroxide (BPO) reacts with alcohols to give benzoates in moderate to good yields. The reaction proceeds with essentially complete inversion of the configuration at the secondary carbinol stereocenters. It is noteworthy that 1,2-diols are benzoylated at the secondary hydroxy group in preference to the primary one (Scheme 46).[85] The product ratio is practically the same as that obtained by the DEAD–$Ph_3P$ procedure.[86] Therefore, as far as benzoylation is concerned, the BPO–$Ph_3P$ procedure seems attractive because the removal of hydrazine dicarboxylate from the desired product is sometimes troublesome in the DEAD–$Ph_3P$ procedure.

## 1.1.3 PREPARATION OF ETHERS

### 1.1.3.1 Cyclic and Acyclic Ethers

Acyclic and cyclic ethers are synthesized by the reaction of activated alcohols with alkoxide or aryl oxide anions. Alkyl halides and epoxides can also be utilized as versatile electrophiles for the preparation

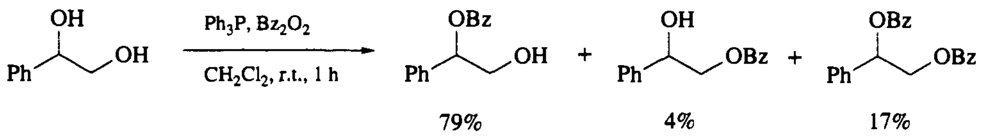

**Scheme 46**

of ethers. Since comprehensive reviews of the preparation of ethers have been published,[2,87] only a limited number of examples will be described in this section.

Of the activated alcohols described in Section 1.1.2.5.1, alkyl sulfonates are convenient alkylating reagents because they can be readily prepared and handled. The correct choice of sulfate–alcoholate combination is often crucial for successful ether synthesis. Thus, for the preparation of cholesteryl ethers from the tosyl derivative of cholesterol and alkoxides, the reaction must be carried out at 110 °C for 2.5 h in a sealed tube. Alternatively, the sodium salt of cholesterol can be reacted with an alkyl mesylate at 80 °C for 1 h in DMF to give the corresponding ether in 62–68% yield.[88]

Benzyl, 4-methoxybenzyl and triarylmethyl groups are used in the protection of the hydroxy groups. Compared to typical benzylation conditions (BnBr, NaH in DMF), benzylation by triflate proceeds under milder conditions without affecting alkali labile groups. Treatment of carbohydrates (**105**), (**106**) and (**107**) with benzyl triflate, generated from benzyl alcohol and triflic anhydride in 2,6-di-*t*-butylpyridine at –70 °C, gives the corresponding benzylated derivatives in 93%, 89% and 60% yields, respectively. Similarly, the methyl ethers are prepared using methyl triflate, but the reaction requires heat and longer reaction time.[69a,89] Benzylation of (**108**) is successfully carried out with preformed benzyl triflate to afford (**109**) in 96% yield without epoxide formation. By the reaction with $K_2CO_3$, (**108**) gives epoxide (**110**).[90] Triflate (**111**) reacts with various nucleophiles ($BzO^-$, $N_3^-$, $RS^-$) to give the corresponding mannopyranosides (**113**) in 82–89% yields. On the other hand, the reaction of (**111**) with NaOMe exclusively gives anhydromannopyranoside (**112**; Scheme 47).[91]

Benzyl trichloroacetimidate (**114a**) reacts with alcohols in the presence of TFA to afford benzyl ethers.[92] 4-Methoxybenzyl trichloroacetimidate (**114b**), which is much more reactive than (**114a**) and very sensitive to strong acids, reacts smoothly with various kinds of alcohol to give the corresponding methoxybenzyl ether. The catalyst used is CSA (10 mol%), PPTS (10 mol%), $TrClO_4$ (3 mol%) or TFA (0.3 mol%). Under these conditions, alcohols having either acid or base labile groups, such as (**115**) and (**116**), are successfully protected (Scheme 48).[93]

Selective protection of the primary hydroxy group in polyols by the trityl group can generally be accomplished by the reaction with trityl chloride in pyridine. The use of DMAP (0.04 equiv.) and $Et_3N$ (1.5 equiv.) facilitates the reaction.[94] Selective phenylation of one hydroxy group of diols can be carried out by the reaction with triphenylbismuth diacetate. While regioselectivity for primary–secondary vicinal diols is poor, only secondary alcoholic functions are converted to the phenyl ether in secondary–tertiary vicinal diols. Although phenylation of glycols occurs smoothly, monohydroxy alcohols are left essentially intact.[95]

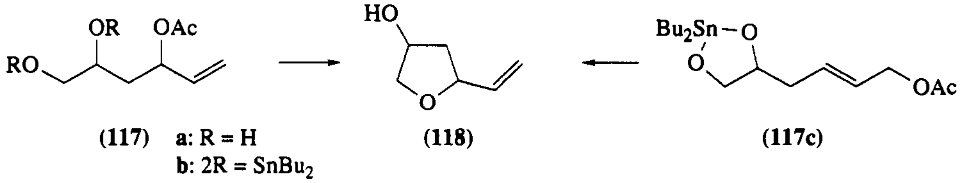
Scheme 48

In view of the fact that many complex dihydro- and tetrahydro-furans possess valued biological properties, a variety of procedures for the construction of such systems has been reported.[2f] The reactivity pattern of the cyclic ether formation with respect to ring size has been briefly discussed.[3i,96]

Of the alkylation systems described in Section 1.1.2.5.1, the DEAD–$Ph_3P$ procedure cannot be used in the preparation of acyclic dialkyl ethers, but alkyl aryl ethers and cyclic ethers have been synthesized. The $Ph_3P$–$CCl_4$ system is also effective for the cyclodehydration of 1,4- and 1,2-diols to tetrahydrofurans and epoxides, respectively.[97]

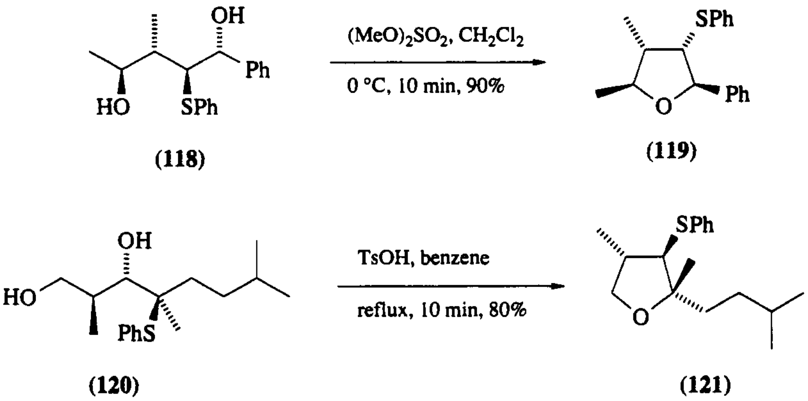
In the presence of a palladium(0) catalyst, allyl acetates having hydroxy functions afford cyclic ethers. Thus, exposure of (**117a**)–(**117c**), 1:1 diastereomeric mixtures, to $[(DBA)_3Pd_2]/CHCl_3$–$Ph_3P$ at room temperature gives rise to the same cyclic ether (**118**) in 92–96% yields as a 9:1 isomeric mixture. No cyclization products derived from the secondary alcohol serving as the nucleophile are detected (Scheme 49). By this procedure, five- to seven-membered cyclic ethers have been prepared.[98]



(117) a: R = H
b: 2R = SnBu2
(118)
(117c)

Scheme 49

The acid-catalyzed cyclodehydration of (±)- and meso-2,5-hexanediol has been shown to proceed with inversion of configuration in most cases, affording *cis*- and *trans*-2,5-dimethyltetrahydrofuran, respectively. However, various extents of racemization are observed in the actions of certain Lewis acids and $H_2SO_4$.[99] The stereospecific cyclization of diols to tetrahydrofurans occurs if phenylthio participation is involved. The reactions of 2-phenylthio-1,4-diols such as (**118**) with dimethyl sulfate afford (**119**) with net retention of configuration, whereas acid-catalyzed cyclizations of 4-phenylthio-1,3-diols such as (**120**) take place with PhS migration and hence inversion at both the migration origin and terminus (Scheme 50).[100]



(**118**) (**119**) (**120**) (**121**)

**Scheme 50**

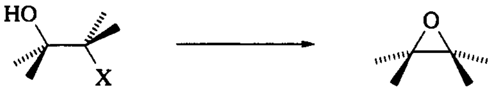
A transition metal catalyzed synthesis of ethers by carbene insertion into the O—H bond has been reported. Not only saturated but also unsaturated alcohols can be utilized in this catalytic process.[101]

Intermolecular and intramolecular oxirane ring opening reactions by alkoxides and phenoxides also provide efficient and stereospecific preparations of acyclic and cyclic ethers. The procedures have been surveyed in detail.[3]

### 1.1.3.2 Epoxides

Perhaps the most widely used procedure for epoxide synthesis is peroxide or peroxy acid oxidation of alkenes, which is discussed in Volume 7, Chapters 3.1 and 3.2.

Another important method involves intramolecular $S_N2$ displacement of an alcohol with an appropriate leaving group in the β-position (**122**; Scheme 51). In this approach, the preparation of β-functionalized alcohols having definite configuration at both the α- and β-carbon atoms is prerequisite. The most promising strategy to achieve the correct construction and configuration of the intermediates is the transformation of natural products by stereochemically unambiguous processes. For details on this approach, the reader is referred to an excellent review.[102]



(**122**)

$X = \text{halogen}, RSO_3, R_2\overset{+}{S}, R_3\overset{+}{P}O$, *etc.*

**Scheme 51**

Stereoselective preparation of precursors to epoxides can also be achieved by the aid of the structure of the substrates, especially in the cyclic systems. Scheme 52 illustrates the stereochemical outcome of epoxide formation *via* the bromohydrin route and the peroxy acid oxidation procedure.[103]

Intramolecular participation of an appropriately placed nucleophile promises to be a useful strategy for the stereocontrolled synthesis of acyclic systems. Thus, halocyclization of unsaturated carboxylic acids, alcohols and functionalized alcohols (**123**) can be effected by a variety of electrophilic halogenating

Bu^t
Bu^t

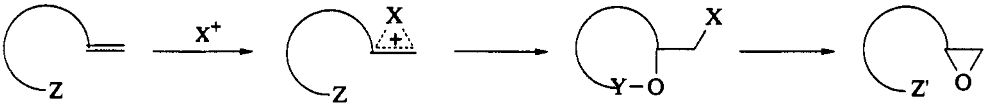
Scheme 52

agents affording stereochemically biased halomethyl heterocycles. Lactones, cyclic carbonates and cyclic phosphates thus formed are in turn converted into epoxides *via* halohydrins (Scheme 53).[104]



**(123)** $Z = CO_2R, OC(O)OR, OP(O)(OR)_2$, *etc.*

Scheme 53

Treatment of homoallylic phosphates with $I_2$ results in the formation of thermodynamically more stable cyclic phosphates which are converted into *erythro*-epoxides with high stereoselectivity (Scheme 54).[105] The procedure (phosphate extension) allows otherwise difficult stereoselective conversion of homoallylic alcohols into 3,4-epoxy alcohols.

Tin(II) triflate mediated cross aldol reactions between α-bromo ketone (**124**; Scheme 56) and aldehydes afford *syn*-α-bromo-β-hydroxy ketones (**125**) with high stereoselectivity. The resulting halohydrins are converted to the corresponding (*Z*)-2,3-epoxy ketones (**126**).[108] Chiral aldehyde (**127**) reacts with lithium alkynide (**128**) followed by mesylation and base treatment to give chirally pure (*E*)-epoxide (**129**). The initially formed alkoxide anion should be trapped *in situ* by mesylation, otherwise partial racemization takes place owing to benzoate scrambling (Scheme 56).[109]

Epoxides can also be prepared from a variety of β-functionalized alcohols such as β-hydroxy sulfoxides,[110] β-hydroxysulfonium salts,[111] β-hydroxy selenides[112] and vicinal diols. In the use of unsymmetri-

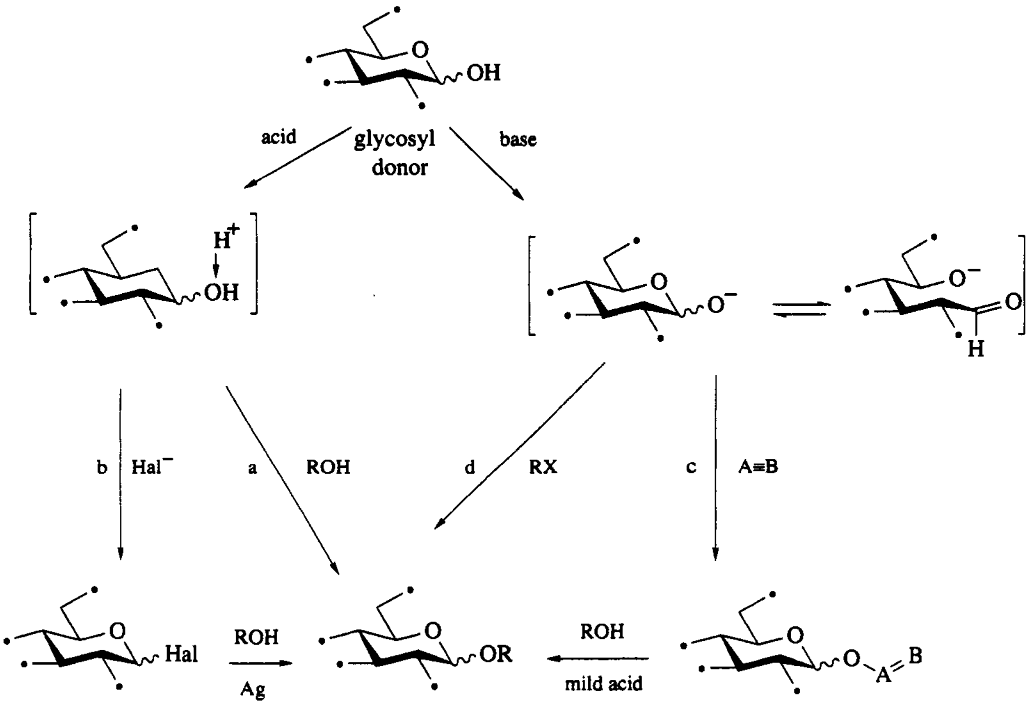
## 1.2.1 INTRODUCTION

Glycoside synthesis is a very common reaction in nature, providing a great variety of compounds, for instance oligosaccharides as such, or glycoconjugates with lipids (glycolipids), proteins (glycoproteins) and many other naturally occurring substances. However, the important biological implications of the attachment of sugar moieties to an aglycon are only now becoming more and more obvious, creating a growing interest in this field. For instance, the presence of complex carbohydrate structures as integral constituents of membranes and cell walls has led to manifold activities in recent research.[1–7] An especially important role amongst these glycoconjugates seems to be played by the glycosphingolipids,[1–3] the glycophospholipids[1] and the glycoproteins.[1–6] Their manifold functions are based on a great structural diversity of the oligosaccharide portion, which is inherent to the variability in glycoside bond formation.[1,4] This point was recently impressively illustrated,[1] rendering oligosaccharides ideal as carriers of biological information and specificity.

This knowledge is based on an enormous extension and improvement of the methodologies for structure determination[8] and for chemical synthesis,[1,2,5,6,9–12] as will be outlined below. The synthesis of glycosides, oligosaccharides and glycoconjugates is characterized by a much larger number of possibilities for coupling than that of other biopolymers, such as peptides or proteins and ribo- or deoxyribo-nucleotides.[1] In contrast to peptides and nucleotides, in which the informational content is determined solely by the number and sequence of different monomer units, the informational content of oligosaccharides is fixed additionally by the site of coupling, the configuration of the glycosidic linkage (α or β) and the occurrence of branching. Thus, oligomers made up of carbohydrates can carry considerably more information per atomic unit than proteins and nucleotides.[1]

The structural variety complicates the synthesis of glycosides and even more so of complex oligosaccharide structures. It has only recently been possible to develop methods for the synthesis of complex oligosaccharides and glycoconjugates. The results obtained in glycoside and saccharide synthesis will be summarized as outlined in Scheme 1 (paths A–D). (a) The Fischer–Helferich method, describing the direct acid-catalyzed acetalization procedures, where direct substitution of the anomeric hydroxy group takes place. (b) The Koenigs–Knorr method and its variants. In the classical Koenigs–Knorr method, and the subsequently developed efficient variants, the generation of glycosyl donor properties is achieved through exchange of the anomeric hydroxy group for a halide leaving group (halide = bromide, chloride and recently fluoride, with some special properties) and reaction of the glycosyl halides in the presence of heavy metal salts. This general principle also includes the use of thioglycosides and 1,2-epoxides as glycosyl donors. (c) The trichloroacetimidate method and other anomeric oxygen activations. The direct base-catalyzed activation of the anomeric oxygen with trichloroacetonitrile (and related compounds; see Section 1.2.4.2) yields *O*-glycosyltrichloroacetimidates, which exert very high glycosyl donor properties under mild acid catalysis. Related approaches *via* sulfonate, phosphate, acetate and orthoester formation respectively are included. (d) The anomeric *O*-alkylation method. The direct anomeric *O*-alkylation of pyranoses and furanoses is a completely different substitution process, requiring 1 equiv. of base for the removal of the anomeric hydroxy group proton.



(a) Fischer–Helferich (acid activation); (b) Koenigs–Knorr (Br, Cl, (I) activation, F activation and RS activation); (c) trichloroacetimidate ($OC(NH)CCl_3$ activation and OAc, $OSO_2R$, $OPO_3R_2$ activation); (d) anomeric *O*-alkylation (base activation)

**Scheme 1** Synthesis of glycosides and saccharides

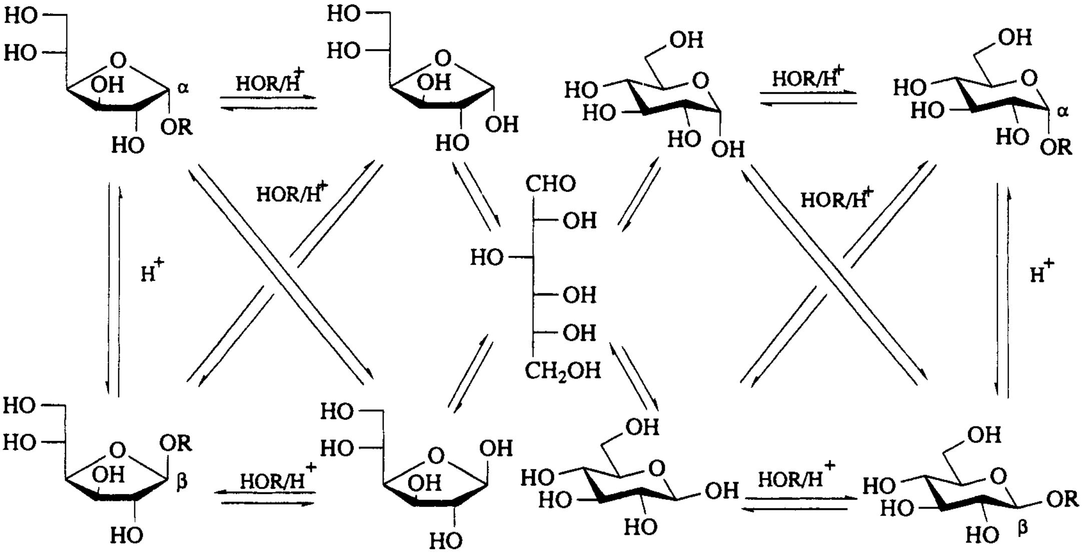
Other methods have gained practically no importance. Special problems in the application of methods (a)–(d) to 2-deoxyglycoside synthesis will be reported in Section 1.2.7.

## 1.2.2 THE FISCHER–HELFERICH METHOD

In a glycoside synthesis, a polyfunctional sugar component must be linked to an acceptor (which is another sugar component in saccharide synthesis). Regioselectivity is generally achieved when the glycosylating component (*i.e.* the glycosyl donor) possesses selectively protected hydroxy groups and an activating group at the anomeric C-atom, and when the component with the acceptor group (*i.e.* the glycosyl acceptor, for instance O-, N-, S- or C-nucleophiles) possesses protective groups at all other acceptor functions (Scheme 1). Thus, complicated protection strategies (Volume 6, Chapter 3.1) and suitable procedures for activation at the anomeric C-atom are required. In addition, the coupling step must occur diastereoselectively with respect to formation of an α- or β-linkage.

In the classical Fischer–Helferich method *O*-glycosides are obtained from hemiacetals and alcohols in an acid-catalyzed reaction as a variant of the common acetal formation (Scheme 1).[9] This reaction is reversible; it is therefore not applicable to the synthesis of compounds with more than one glycoside bond (*i.e.* to the synthesis of oligosaccharides and glycoconjugates) because other glycosidic bonds will be affected. In addition, the diastereocontrol at the anomeric position is based on thermodynamic energy differences between the corresponding α- and β-anomers. The axial position for the anomeric OR group is disfavored by steric arguments (unfavorable 1,3-diaxial interactions) and favored by the anomeric effect (favorable stereoelectronic interactions between the ring oxygen and the anomeric carbon–oxygen bond).[13] These two opposing effects often have similar magnitudes, therefore usually an anomeric mixture of products is obtained, or, due to a slight preponderance of the anomeric effect, more of the α-anomer is formed.

The merits of the Fischer–Helferich method today are mainly in its use for the synthesis of simple glycosides required as starting materials in oligosaccharide synthesis and as chiral synthons.[14] The strategy for sugar protection usually starts with the formation of a methyl, benzyl or allyl glycoside directly from the unprotected sugar, followed by selective introduction of additional protective groups (benzylidene, isopropylidene, benzyl, silylacetyl, benzoyl, *etc.*). Due to ring–chain tautomerism (Scheme 2), with excess alcohol and acid as catalyst, α- and β-furanosides and α- and β-pyranosides can be obtained, leaving three hydroxy groups unprotected in the case of pentoses and four in the case of hexoses. The result is dependent on the individual sugar and the reaction conditions. Due to the ring strain, other glycoside ring sizes are not commonly found and furthermore the open chain *O,O*-acetal is not formed *via* this route. Furanose formation is usually faster than pyranose formation, a phenomenon also typical for other saturated ring closure reactions.[15] However, the occurrence of several acid-catalyzed equilibration reactions (as indicated in Scheme 2) with different kinetics makes product control difficult. Therefore the



Scheme 2

search for procedures resulting in the convenient isolation of one product has gained tremendous importance. Some typical examples are given in Table 1.[16–31]

---

[a] References for the syntheses are given in brackets.

The combination of this simple acid-catalyzed glycoside synthesis with additional acetal formations in the presence of a ketone (mainly acetone and cyclohexanone) furthers the versatility of this method. Thus, from *O*-unprotected hexoses and pentoses respectively, in convenient acid-catalyzed procedures compounds with only one or two *O*-unprotected hydroxy groups are directly accessible, providing convenient functional group control in subsequent reactions (Table 1; in some cases even the sugar aldehyde group is left unprotected). Most of these compounds are now commercially available. They are extensively used as starting materials in research laboratories and even in technical processes. For instance, diacetone sorbose (obtained from acetone and L-sorbose under acidic conditions) is an intermediate in the commercial vitamin C synthesis[32] and D-arabinose derivatives could become starting materials for a short (+)-biotin synthesis.[33,34]

However, another application of the Fischer–Helferich method clearly exhibits its limitations. Long chain alkyl glycosides have gained interest as nonionic surfactants.[35] Their technical synthesis is based on acid catalysis of the reaction between glucose and alcohol. Due to the inherent solubility problems, typical drawbacks of the Fischer–Helferich method are encountered: the technical product consists of a mixture of different anomers and, due to the fact that excess alcohol cannot be used for solubilization of the reaction mixture, reaction of glucose with itself is also found.

Due to the drawbacks of the Fischer–Helferich method it was early recognized that other approaches to glycoside and saccharide synthesis had to be introduced.

## 1.2.3 THE KOENIGS–KNORR METHOD AND ITS VARIANTS: ACTIVATION THROUGH ANOMERIC OXYGEN EXCHANGE REACTIONS

### 1.2.3.1 General Aspects of Glycoside Bond Formation

A versatile and generally applicable method for a diastereocontrolled glycoside and saccharide synthesis seems to necessitate a two-step procedure with the following requirements.[1]

The first step, activation of the anomeric center generating the glycosyl donor, requires: (i) convenient formation of a sterically uniform glycosyl donor; (ii) adoption, according to choice, of either α- or β-configuration; and (iii) thermal stability of the glycosyl donor at least to room temperature; eventually chromatographic purification should be possible.

The second step, the glycosyl transfer to the acceptor providing the glycoside, the oligosaccharide or the glycoconjugate, requires: (i) catalysis of the glycosyl transfer by simple means; (ii) irreversibility of the reaction; (iii) that the configuration of other glycosidic bonds is not affected in the process; (iv) high chemical yield; and (v) high α- or β-selectivity *via* diastereocontrolled inversion or retention of configuration at the anomeric center (usually attained in a kinetically controlled reaction).

### 1.2.3.2 The Koenigs–Knorr Method: Bromide and Chloride as Leaving Groups

In the classical Koenigs–Knorr method, dating from 1901,[36] and the subsequently developed efficient variants, the activation step is achieved through the formation of glycosyl halides (halogen = bromine and chlorine) and their reaction in the second step, the glycosyl transfer step, in the presence of heavy metal salts (preferentially silver and mercury salts). This method has been critically reviewed,[1,5] giving the following general picture.

#### *1.2.3.2.1 Glycosyl halide formation*

The exchange of the anomeric hydroxy group for bromine or chlorine, carried out with typical halogenating agents (and all other hydroxy groups *O*-protected), leads mainly to the product with the halogen atom in an axial position. Because the subsequent discussion is mainly restricted to the important sugars D-glycopyranose (Glc), 2-acetamino-2-deoxy-D-glucopyranose (GlcNAc), D-galactopyranose (Gal), 2-acetamino-2-deoxy-D-galactopyranose (GalNAc) and D-mannopyranose (Man), which prefer the $^1C_4$ conformation, axial orientation at the anomeric position corresponds with the α-anomer and equatorial orientation with the β-anomer, respectively.

### *1.2.3.2.2 Glycosyl halide stability and reactivity*

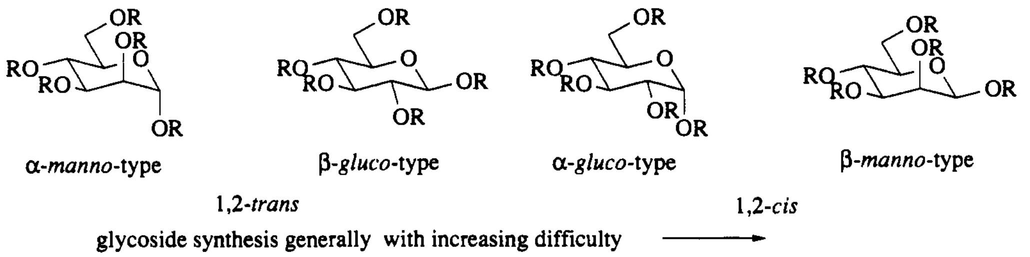
The stability and reactivity of the glycosyl halides is greatly dependent on the halogen, the sugar and the protective groups. The thermal stability increases from bromide to chloride and by substituting electron-donating protective groups for electron-withdrawing protective groups. Dramatic changes in stability are observed; thus the well-known acetobromoglucose (2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide) can be readily prepared and stored at 0 °C, whereas the frequently used 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranosyl bromide is thermally unstable as low as –78 °C (glycosyl iodides are usually too unstable). Therefore, many glycosyl halides are prepared *in situ* and used without further purification, thus necessitating the use of compounds which are frequently sterically nonhomogeneous and sometimes even impure. In addition, the glycosyl halides are highly sensitive to hydrolysis.

The reactivity of the glycosyl halides increases in reverse order compared with stability; protective groups at different positions exert 'remote electronic effects'. The influence of these groups does not depend only on the distance to the anomeric carbon atom;[37] thus electron-withdrawing *O*-protective groups at C-4 lower the C-1 reactivity quite strongly due to through-bond interactions.

### *1.2.3.2.3 α/β-Selectivity in glycoside synthesis*

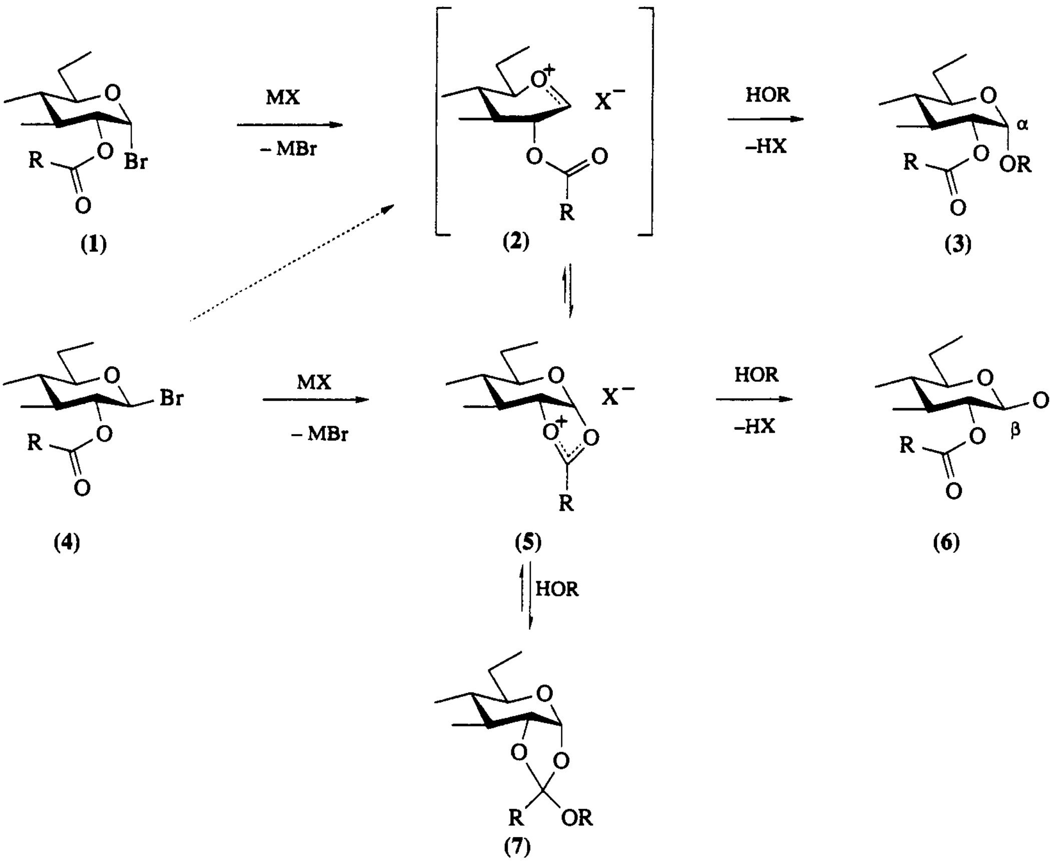
A stereocontrolled nucleophilic substitution of the glycosyl halogen by an $S_N2$ mechanism would provide the β-glycosides from the generally readily available α-glycosyl halides. Thus the only existing problem would be the generation of the thermodynamically less stable β-halogenoses. However, the situation is much more complicated, because most glycosyl acceptors are not reactive enough for a simple base-catalyzed nucleophilic substitution at the anomeric center. Therefore, the reactivity of the glycosyl halide itself has to be adjusted to the special synthetic problem by varying the halide and the protective group pattern, and, above all, by selecting a proper halophilic 'catalyst' (required in equimolar amounts) as a coactivator. In addition, appropriate solvents and temperatures have to be chosen in relation to the glycosyl acceptor reactivity (which can also be varied by varying the protective group pattern). The fact that glycosyl halides will eventually exhibit the features of α-halogen ethers implies that at least the reactive representatives will favor $S_N1$-type mechanisms which are not stereoelectronically controlled. Therefore all the other factors mentioned above will play important roles in diastereoselection.

Due to the general structure of hexoses (and pentoses) and due to the importance of the hydroxy group next to the anomeric position, four different structural situations are generally differentiated (Scheme 3). The ease of formation of these different anomeric linkages is mainly dependent on the strength of the anomeric effect, which is comparatively stronger in the α-*manno*-type than in the α-*gluco*- (and the α-*galacto*-) type sugars, and possible neighboring group participation of protective groups at the functional group at C-2. Thus the readily available α-glucosyl halide (**1**; Scheme 4), presumably *via* a tight (or a solvent-separated) ion pair (**2**), or the β-glucosyl halide (**4**), collapses to a dioxolanium intermediate (**5**), which is attacked by the glycosyl acceptor almost exclusively from the β-face, cleanly providing β-glucopyranosides (**6**). In the reaction course conformational changes to half-chair forms are required for oxygen lone pair orbital overlap with the C-1 carbonium ion. Due to the intramolecularity of formation of (**5**), bimolecular attack at (**2**) from the α-face, providing α-glucopyranosides (**3**), can be obtained only with difficulty, usually necessitating thermodynamic control. Obviously orthoester (**7**) formation is a competing side reaction, which can be reversed by acid treatment. Therefore orthoesters (**7**) can also be successfully applied to β-glucopyranoside (**6**) synthesis (see Section 1.2.4.1)



Typical examples – *gluco*-type: D-Glc, D-GlcNAc, D-GlcA, MurAc, D-Gal, D-GalNAc, L-Fuc;
*manno*-type: D-Man, L-Rha

**Scheme 3**



**Scheme 4**

These considerations explain the experimentally found ease of formation of α-*manno*-type structures (Scheme 3) because they are favored by the anomeric effect and by neighboring group participation (Scheme 3). β-*Gluco*-type structures are also readily accessible when neighboring group participation is applicable. However, the formation of α-*gluco*-type structures depends strongly on thermodynamic control (or $S_N2$-type reactions) without recurrence to neighboring group participation. Obviously, the formation of β-*manno*-type structures is supported neither by the thermodynamic anomeric effect nor by neighboring group participation. It is strictly dependent on an $S_N2$-type reaction starting from the readily accessible α-*mannosyl*-type halides. Therefore this structural type is most difficult to prepare.

### *1.2.3.2.4 Other variables in glycoside bond formation*

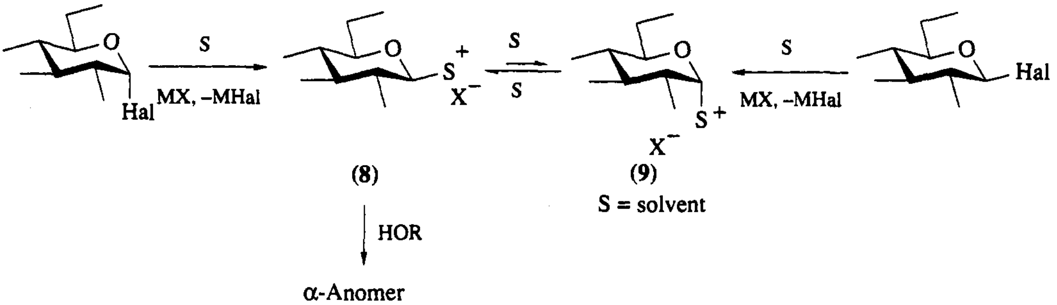
The above conclusions concerning the stability and reactivity of glycosyl halides and their diastereocontrol in substitution reactions with glycosyl acceptors have to be complemented by the other variables in glycoside bond formation.

*(i) The catalyst*

As catalysts (or coactivators, required in at least equivalent amounts), various silver or mercury salts are applied. Mercury-containing components, especially $Hg(CN)_2$ in nitromethane as solvent or cosolvent, were introduced by Helferich and coworkers,[38] and are therefore often referred to as 'Helferich conditions'. Important aspects are differences in reactivity and the generation of equivalent amounts of acid and/or water in the course of glycoside bond formation. For the most common catalysts the following order of reactivity has been generally confirmed: $AgOTf/Ag_2CO_3 > AgClO_4/Ag_2CO_3 > Hg(CN)_2/HgBr_2 > Hg(CN)_2$.[5] The formation of acid can be circumvented by the addition of $Ag_2CO_3$ in combination with catalytic amounts of AgOTf or $AgClO_4$ and the use of a base, for instance collidine. Water is commonly removed with Drierite or molecular sieves (3Å and 4Å).

*(ii) The solvent*

Solvents which are poor donors are commonly used in glycoside synthesis, for instance dichloromethane, cyclohexane or petroleum ether. These solvents favor *S*N2-type reactions. Solvents which are better donors, for instance ethers (diethyl ether, THF, *etc.*), acetonitrile, pyridine, nitromethane *etc.*, each result in a typical change in the reaction course due to their different participation in the stabilization of the reaction intermediates. With ethers, acetonitrile and pyridine participation leads to onium-type intermediates (Scheme 5; **8** and **9**), which eventually provide, *via* fast equilibration, mainly the β-anomer (**8**), due to their higher thermodynamic stability, based on the 'inverse anomeric effect'.[13,39] Thus α-product formation is often favored in these solvents (see Section 1.2.3.2.5). Solvents with even higher dielectric constants commonly result in lower diastereocontrol in glycoside synthesis.



**Scheme 5**

Recently, *in situ* generation of onium-type intermediates from pentenyl glycosides was suggested by Fraser-Reid and coworkers[40] for glycoside synthesis. Thus far the α,β-selectivities in this process have mainly been found to be low.

*(iii) The temperature*

Due to the low thermal stability of many glycosyl halides reaction temperatures above room temperature are usually not applied. The general tendency to favor the stereoelectronically controlled *S*N2-type reaction is reason to use reaction temperatures as low as possible. However, solubility and reactivity are commonly the decisive factors for reaction temperature selection.

*(iv) The acceptor*

The acceptor reactivity exhibits big differences, which are due to steric, stereoelectronic (*e.g.* anomeric configuration) and inductive (*e.g.* electronic character of protective groups effects), with the steric effect usually predominating. When all groups are equatorial (for instance *gluco*-type in $^{1}C_4$-conformation) the following reactivity order is observed: 6-OH > 3-OH > 2-OH > 4-OH.[5] Axial hydroxy groups are usually less reactive than equatorial hydroxy groups (3-OH *versus* 4-OH in galactopyranose). These observations were successfully applied in regioselective saccharide syntheses with partially *O*-protected glycosyl acceptors (see Section 1.2.3.2.5).

### *1.2.3.2.5 Examples*

Prominent oligosaccharide structures found in glycoconjugates include blood group antigenic determinants, the carbohydrate–peptide connections of *O*- and *N*-glycoproteins, the carbohydrate–ceramide connections of glucosphingolipids, fundamental structures of *O*- and *N*-glycoproteins and of glycosphingolipids, and oligosaccharide units of lipopolysaccharides;[1–7] these have attracted the interest of synthetic chemists. The versatility of the Koenigs–Knorr method has been demonstrated in this area in the last 20 years.[5]

The ease of α-*manno*-type connection starting from 2-*O*-acetyl-α-mannopyranosyl bromides (**10**) and (**11**) is exhibited in the synthesis of fragments (**14**) of the *N*-glycosidically linked carbohydrate portion (**13**) in glycoproteins (Scheme 6).[41] However, other important aspects of efficient oligosaccharide syntheses are also exhibited in this example: these are partial *O*-protection for starting material synthesis with the help of regioselective stannylation and subsequent benzylation, regioselective mannosylation and block synthesis for the attachment of the lactosaminyl residue. The required lactosaminyl donor (**12**) is obtained from lactal *via* azidonitration by the cerium ammonium nitrate route introduced by Lemieux and coworkers.[42]

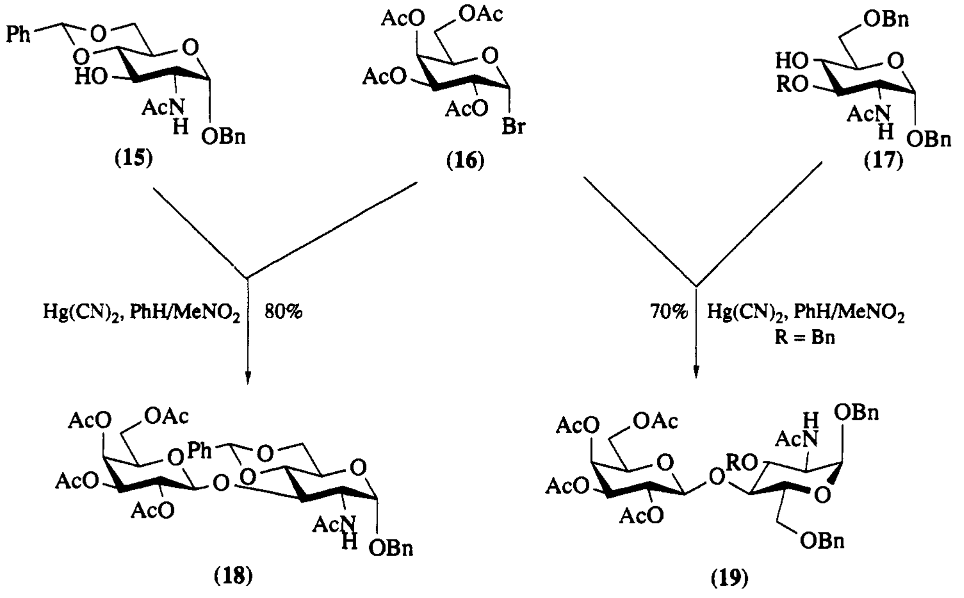
**Scheme 6**

The α-Rhamnopyranosyl connection often met in repeating units of lipopolysaccharides is obtained by analogous procedures.[5,43]

β-Glucopyranosyl and β-D-galactopyranosyl connection (β-*gluco*-type) can be readily attained if the reactivity of 2-*O*-acyl-protected donors is sufficient for the acceptor reactivity. Scheme 7[44] demonstrates this difference clearly. The galactosyl donor (**16**) reacts with the acceptor (**15**) cleanly to give the β-disaccharide (**18**). However, under the same conditions compound (**17**) with R = acetyl gives practically no product, and compound (**17**) with R = benzyl is still much less reactive than compound (**15**), although the corresponding β-disaccharide (**19**) is obtained in good yield after longer reaction time.

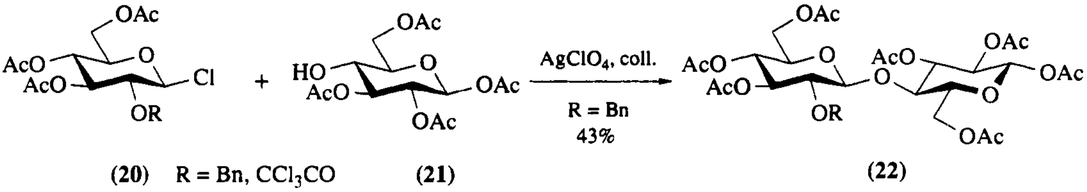


**Scheme 7**

Neighboring group participation for β-glucosamine and β-galactosamine connection is best achieved with the 2-deoxy-2-phthalimido group. Because of the excellent leaving group properties of the generated oxazolinium intermediate, high yields and high β-selectivities are usually observed (Scheme 6).[41] The required removal of the phthalimido group (with hydrazine) for the subsequent *N*-acetylation (to provide the acetamino compounds found in natural products) has already inspired work using the 2-acetamino group as a neighboring group in β-selective glycoside syntheses. However, due to the presence of an NH group, stable oxazolines are obtained from the corresponding glycosyl halides. Under strong acidic catalysis (attack of the acid at the oxazoline nitrogen) these intermediates exert glycosyl donor properties with reactive acceptors possessing the required acid stability.[5]

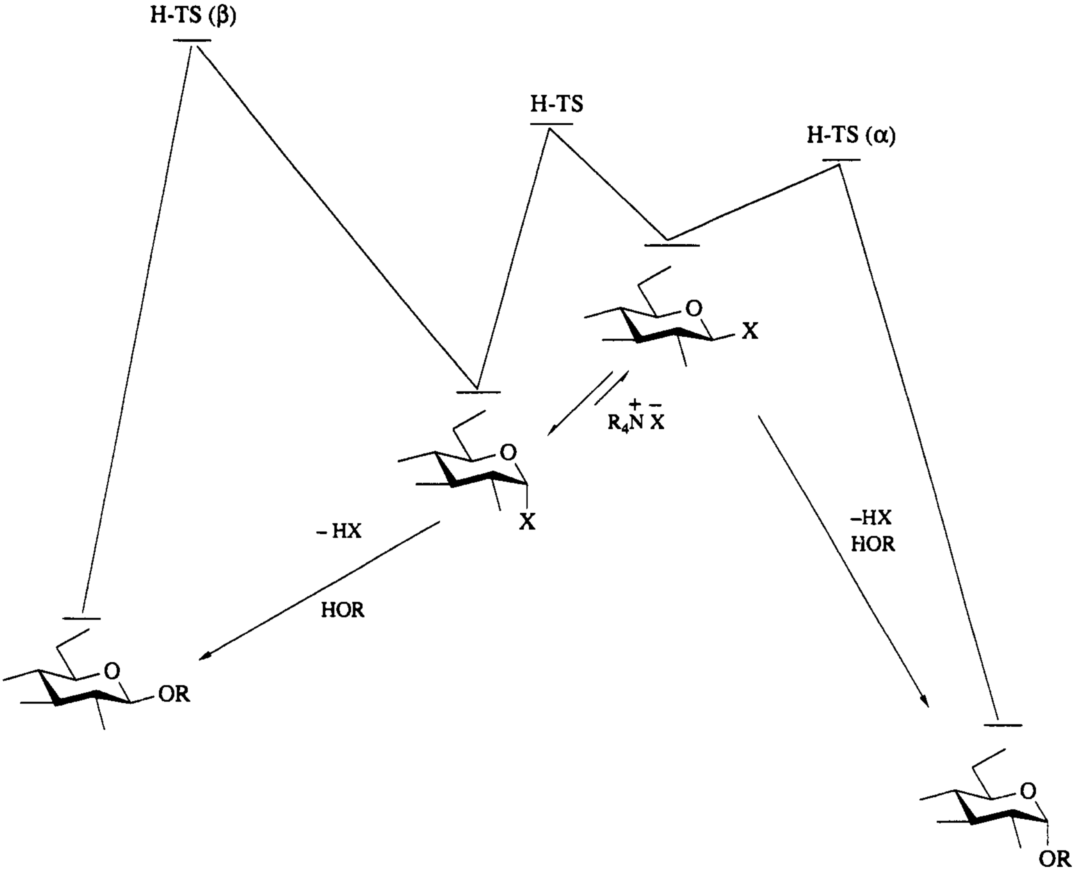
The investigation of 2-azido-2-deoxy sugars in glycoside synthesis has demonstrated that this group is largely a nonparticipating group. It was therefore mainly applied to corresponding α-*gluco*-type syntheses.[5]

The frequent occurrence of the α-D-galactopyranosyl, 2-acetamino-2-deoxy-α-D-galactopyranosyl, α-L-fucopyranosyl and α-D-glycopyranosyl connections in glycosides and saccharides has intensified the search for appropriate variations of the Koenigs–Knorr method. Obviously, nonparticipating groups (*e.g.* 2-*O*-benzyl, 2-azido-2-deoxy, *etc.*) and β-glycosyl halides were best applied to promote an $S_N2$-type reaction. The viability of this approach is demonstrated in Scheme 8,[45] where, with the help of electron-withdrawing *O*-protection in the donor (**20**) and the acceptor (**21**), the cellobiose derivative (**22**) is obtained. The decreased reactivity had to be overcome by the use of strong silver catalysts.



**Scheme 8**

All this points to finding a means for the generation of the less stable β-glycosyl halides. This problem was solved by Lemieux and coworkers[46] with the help of the '*in situ* anomerization' of α-halogenoses with halide ions. Thus the β-halogenoses which are obtained are higher in ground state energy and more reactive towards glycosyl acceptors than α-halogenoses, preferentially affording, *via* an $S_N2$-type reaction, the α-glycosides. This is qualitatively demonstrated in Scheme 9. For the transition state geometries, half-chair-like geometries are suggested. Lemieux and coworkers[47] applied tetraalkylammonium halides for catalysis of this reaction, which turned out to be efficient only for reactive glycosyl donors. Later it was found by Paulsen and coworkers[48] that other soluble catalysts ($Hg(CN)_2$, $HgBr_2$, $AgClO_4$, AgOTf) are more efficient, providing α-glycosides using less reactive glycosyl donors under mild conditions. For instance, the important A, B and H blood group antigenic determinants were obtained with the help of this method (Scheme 10).[49,50] The synthesis of the H and B (type 2) determinants is exhibited starting from the lactosamine acceptor (**23**), which is first connected with the fucosyl donor (**24**), providing trisaccharide (**25**), and then with the galactosyl donor (**26**) to yield the tetrasaccharide (**27**). Subsequent deprotection of saccharides (**25**) and (**27**) provided the desired blood group determinants. In this α-glycosylation procedure, intermediates with the counterions of the catalysts or complexes with the complete catalyst are presumably generated[5] which correspond to β-halogenoses in their reaction behavior. This relates this process to the influence of participating solvents, which exert a similar effect. This could be successfully demonstrated in α-D-glucopyranuronic acid synthesis (Scheme 11).[51] Acetonitrile proved to be particularly suitable; with the glycosyl donor (**28**) excellent yields of α-glycosides (**29**) were obtained with various acceptors. Nitrilium–nitrile association, as shown in structures (**30**), presumably hinders attack by the acceptor at the nitrilium carbon.



H-TS = half-chair transition state

**Scheme 9** *In situ* anomerization procedure

β-*Manno*-type connection became important because this glycoside bond was found in the branching position of *N*-glycoproteins. Previous investigations with α-mannosyl bromide and reactive acceptors in the presence of insoluble silver oxide[52] inspired Paulsen and coworkers[53] to develop an insoluble heterogeneous silver silicate catalyst system, which proved to be very successful in β-mannopyranoside formation. Later silver zeolite was introduced by Garegg and coworkers[54] for the same purpose. A key synthesis was the β-mannopyranosyl connection to the 4-O of *N*-acetylglycosamine found in *N*-glycoproteins. An example of these investigations is exhibited in Scheme 12.[55] The mannosyl donor (**31**), with a nonparticipating 2-O protective group, reacts in good β-selectivity with the 1,6-anhydro-2-azidoglu-

β-Rhamnopyranoside structures, found in repeating units of the lipopolysaccharides of bacteria, have been also obtained with the help of these procedures.

### *1.2.3.2.6 Summary*

In conclusion, the results with the Koenigs–Knorr method can be summarized as follows.

Firstly, the reactivity of the glycosyl donor can be varied over wide ranges by the choice of the halogen, the protecting group pattern, the catalyst, the solvent and the temperature. In this way the glycosyl donor reactivity can be adjusted to the glycosyl acceptor reactivity (which can also be varied).

Secondly, diastereoselectivity in the glycoside formation is attained by: (i) participation of neighboring groups for β-glycosides of glucose, glucosamine, galactose and galactosamine and for α-glycosides of mannose, fucose and rhamnose; (ii) *in situ* anomerization of the α-glycosyl halide to the more reactive β-glycosyl halide, which reacts preferentially to give the more stable α-glycosides of glucose, glucosamine, galactose and galactosamine (*i.e.* exploitation of the thermodynamic anomeric effect); and (iii) heterogeneous catalysis, which gives good results in the difficult formation of the β-mannose and β-rhamnose linkage.

The application of these observations has also led to many excellent results in *N*-glycoside synthesis. (The discussion of the special aspects of *N*- and *C*-glycoside synthesis is beyond the scope of this chapter.) However, severe, partly inherent disadvantages of the Koenigs–Knorr method could not be overcome. These include the low thermal stability and the sensitivity to hydrolysis of many glycosyl halides, and the use of at least equimolar amounts of heavy metal salts as 'catalysts', which are partly toxic or even explosive, to mention only a few aspects. This had led to an increased search for improved methods applicable also to large scale preparations.

### 1.2.3.3 Fluoride as Leaving Group

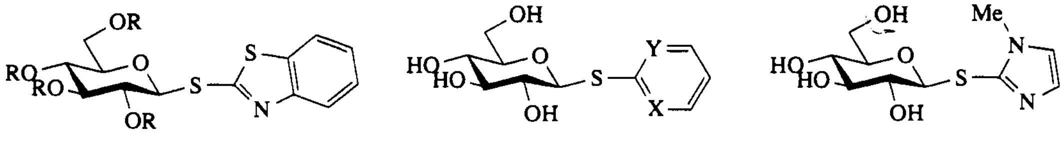
For the generation of glycosyl donor properties, other anomeric oxygen exchange reactions have been investigated. Closely related to the Koenigs–Knorr method, where bromide and chloride are the leaving groups, fluorine has been introduced as a leaving group by Micheel and coworkers (Scheme 1)[56] and has recently been investigated for glycoside synthesis.[1,5,6,12] The higher thermal stability and the higher stability towards many reagents is due to the higher strength of the carbon–fluorine bond as compared to the other carbon–halogen bonds. This enabled even base-catalyzed modifications of unprotected hydroxy groups in the presence of an anomeric fluorine atom.[57] For instance, successful *O*-benzylation of *O*-unprotected α-D-glucopyranosyl fluoride was recently described, exhibiting possible advantages in terms of the strategy of glycoconjugate synthesis.[57] However, the higher strength of the carbon–fluorine bond may concomitantly lower the glycosyl donor properties of glycosyl fluorides. Therefore, specifically fluorophilic promoters were searched for. The $SnCl_2/AgClO_4$ system was introduced by Mukaiyama and coworkers[58] and applied by several groups[59] to glycoside syntheses, resulting in good yields and reasonable α-selectivity with nonparticipating 2-*O*-protective groups. In addition, several methods for the synthesis of glycosyl fluorides were recently reported.[59,60]

Because of the complexity of the $SnCl_2/AgClO_4$ catalyst system several other fluorophilic Lewis acids were investigated as catalysts in this reaction, for instance $SiF_4$,[61] $SnF_4$,[62] $TiF_4$,[62] $BF_3{\cdot}OEt_2$[63] and TMSOTf.[61] Thus with relatively reactive acceptors good glycoside yields were usually obtained; however, good diastereoselectivities were generally only observed for reactions with 2-*O*-participating groups. In cases with nonparticipating groups, the α:β ratio of the products depends on the solvent used rather than on the stereochemistry of the glycosyl fluoride, disproving a direct $S_N2$ reaction course as expected due to the special character of the carbon–fluorine bond. Even a retentive glycoside formation mechanism has been discussed for the $TiF_4$ catalyst.[62,64]

Relatively few applications of glycosyl fluorides in complex oligosaccharide syntheses have been reported thus far.[65] Therefore a general statement of the importance of glycosyl fluorides as glycosyl donors is not possible. Up to now the value of glycosyl fluorides seems to be limited. Glycosyl fluorides have also proved useful in the synthesis of *C*-glycosides.[63a,66]

### 1.2.3.4 Sulfur as Leaving Group

Recently thioglycosides, where the anomeric oxygen is replaced by an alkyl- or aryl-thio group, have attracted considerable attention as glycosyl donors (Scheme 1).[67] As with the glycosyl fluorides, thioglycosides offer efficient temporary protection of the anomeric center, and, in addition, several sulfur-specific activation reactions for generating glycosyl donor properties exist. Particularly obvious is the selective activation of thioglycosides by thiophilic metal salts. These include mercury(II) salts ($HgSO_4$,[68] $HgCl_2$,[69] PhHgOTf,[70] $Hg(OBz)_2$,[71] $Hg(NO_3)_2$[72]), copper(II) triflate[73] and lead(II) perchlorate.[74,75] However, besides the disadvantageous use of heavy metal salts, the activation itself was too weak to be of general applicability to glycoconjugate synthesis. The problem was partly circumvented by using heterocyclic thioglycosides.[75,76] For instance, Mukaiyama and coworkers[73] used benzothiazolyl thioglucoside (**37**; Scheme 13) in the presence of $Cu(OTf)_2$ as catalyst. Hanessian and coworkers[72] studied the reaction of the *O*-unprotected glucosyl thio heterocycles (**38**) and (**39**) with reactive glycosyl acceptors, employing $Hg(NO_3)_2$ as the catalyst and acetonitrile as the solvent. They obtained *O*-glycosides and the disaccharide Glc(1 → 6)Gal in good yields, but with only modest α/β selectivities. Comparative studies on the effect of proton activation with phenyl thioglucoside (**38**; X = Y = CH) and pyridyl thioglucoside (**38**; X = N, Y = CH), demonstrated the dramatic effect of the heteroatom (termed 'remote activation') as a basic anchor for the proton, resulting in a better leaving group due to the electron-withdrawing character. Not surprisingly, this kind of approach to glycoside synthesis has been successfully applied to the more reactive 2-deoxyglycosyl donors (see Section 1.2.7), for instance in the synthesis of erythromycin,[74] avermectin[75] and digitoxin.[69]



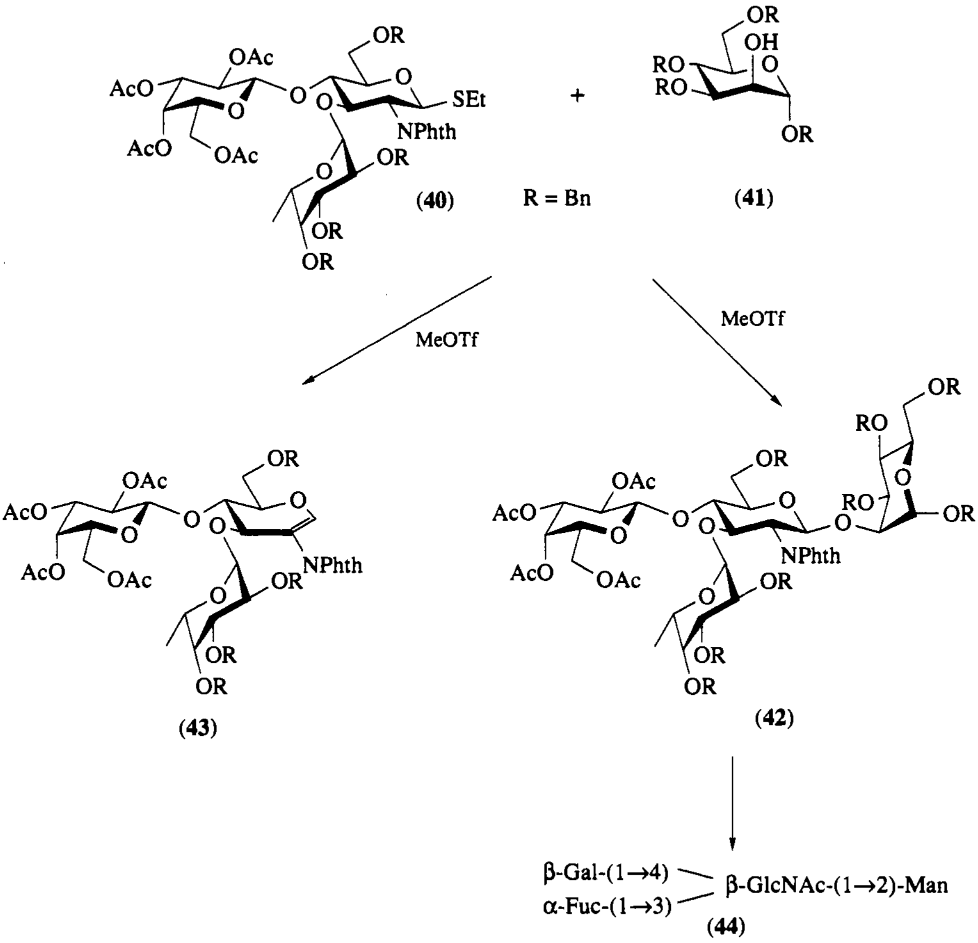
(**37**) R = Bn (**38**) (**39**)

X = N, Y = CH; X = Y = N; X = Y = CH

Scheme 13

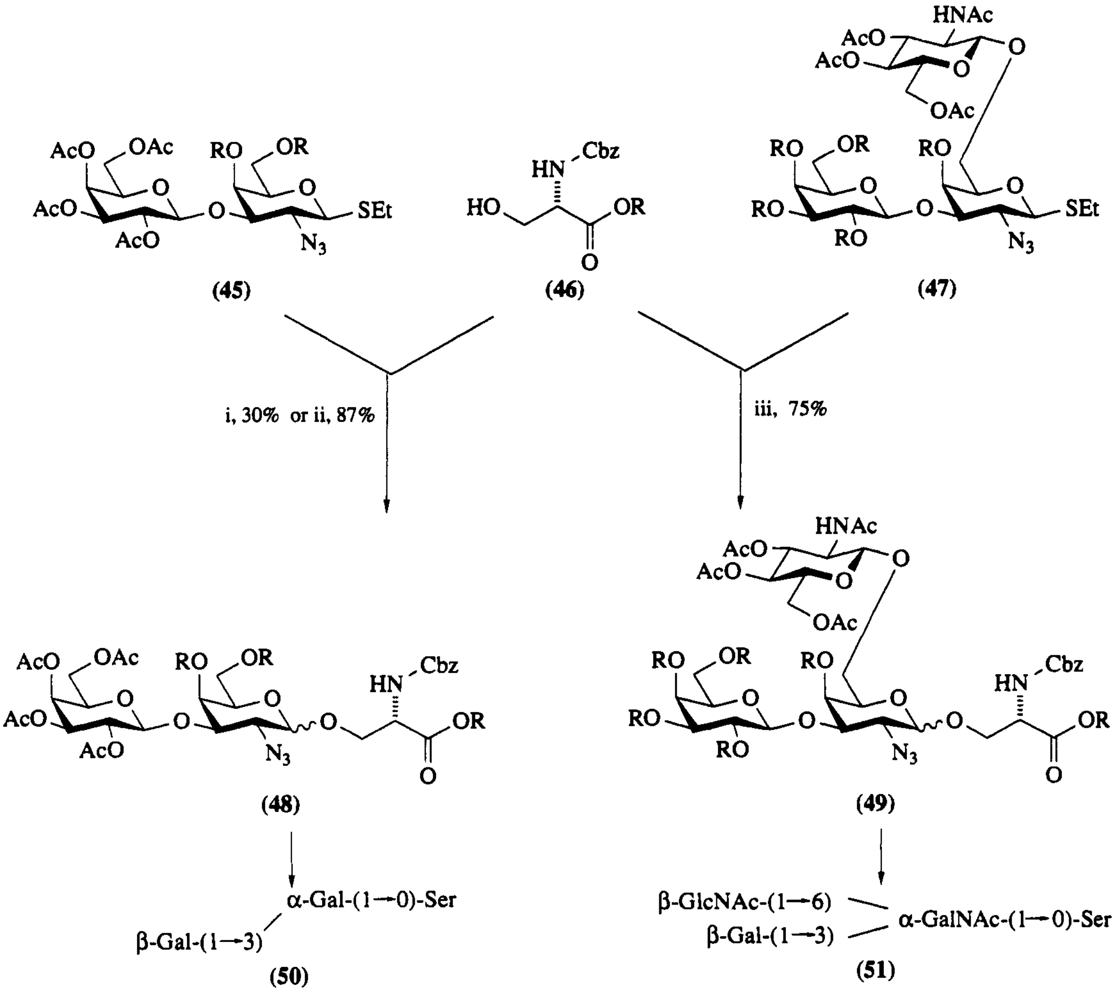
Besides metal salts (and protons), bromonium and chloronium ions are also highly thiophilic. Recent work has demonstrated that, in a two-step process, thioglycosides can first be transformed with bromine and chlorine into the corresponding glycosyl halides (providing the thermodynamically more stable α-halides), thus subsequently enabling the application of the Koenigs–Knorr method.[67,77] If the counterion of the halonium is a poor nucleophile (for instance in *N*-bromosuccinimide), then direct reaction with alcohols as competing *O*-nucleophiles should be preferred. This has been confirmed[72] and, starting from phenyl thioglycosides, a wide scope for this reaction observed;[76] however, low α,β-selectivities were frequently obtained.

Sulfonium, ammonium and phosphonium groups are suitable as leaving groups for nucleophilic displacement reactions at the anomeric center. Schuerch and coworkers[78] have studied these groups and found the following order of reactivity: sulfonium > ammonium > phosphonium compounds, putting the interest mainly on thioglycosides. Thus Lönn reported good glycosidation results for sulfonium leaving groups obtained from alkylthioglycosides and methyl triflate.[79,80] One example is exhibited in Scheme 14.[79] Starting from thioglycoside (**40**) and the mannose acceptor (**41**), owing to phthalimido group control the β-connected tetrasaccharide (**42**) was obtained in good yield. The corresponding unprotected compound (**44**) has been found as a constituent of glycoproteins in the urine of patients suffering from fucosidosis.[80] 1,2-Elimination in this glycosidation procedure, previously reported by Kronzer and Schuerch,[78] was also observed as a competing reaction leading to the glycal derivative (**43**). The low α/β-selectivity observed for nonparticipating 2-*O*-protective groups, the health hazard of methyl triflate and the formation of methylation products in other side reactions are additional disadvantages of this methodology.[79] However, dimethyl(methylthio)sulfonium triflate (DMTST), recently introduced by Fügedi and Garegg,[81] is highly thiophilic and gives rise to faster glycosylations than does methyl triflate. Glycosyl donors with neighboring group partication during reaction generate 1,2-*trans*-linked glycosides (α-*manno*-type, β-*gluco*-type) in excellent yields and virtually complete stereospecificity. However, with nonparticipating groups the α/β-selectivity is usually low.[79] Recent application for generating the α-



Scheme 14

*gluco*-type linkage found in *O*-glycoproteins of the mucin-type core structures (**50** and **51**; Scheme 15) met with limited success.[82] The donor properties of compounds (**45**) and (**47**) towards serine derivative (**46**) were low with methyl triflate but excellent with DMTST, giving the saccharides (**48**) and (**49**). Good α-selectivity was only obtained for (**45**).



i, MeOTf, 8 d (α:β ≈ 4:1); ii, DMTST, 12 h (α:β ≈ 5:1); iii, DMTST, 1 h (α:β ≈ 1:2)

**Scheme 15**

Due to the interest in thioglycosides, the methods of their synthesis from glycosyl halides with thiolates or by *S*-alkylation of 1-thioaldoses[83] have been complemented by new methods.[76,84]

Glycosyl disulfides, sulfonic acids and sulfones have not exhibited interesting glycosyl donor properties.[85]

### 1.2.3.5 Anhydro Sugars as Glycosyl Donors

1,2-Anhydro sugars promise good glycosyl donor properties due to the ring strain in the alkoxy epoxide moiety. Brigl's anhydride was thus used for the synthesis of disaccharides,[86] iridoid glycosides[87] and aryl glycosides;[88] however, only modest results were obtained. Obviously, as stated earlier,[1] the possibilities of this reaction are not exhausted. Therefore renewed interest in this reaction seems promising.[89]

Other 1,*x*-anhydro sugars (*x* > 2), possessing lower ring strain, exhibit lower reactivity.[1]

## 1.2.4 THE TRICHLOROACETIMIDATE METHOD AND OTHER ANOMERIC OXYGEN ACTIVATION METHODS FOR GLYCOSIDE SYNTHESIS

### 1.2.4.1 Introduction and Earlier Examples of Oxygen Activation

The requirements for glycoside synthesis introduced in Section 1.2.3.1 are obviously not met by any of the methods described. However, it seems that the general strategy for glycoside synthesis is reasonable, namely: (i) that the first step should involve a sterically uniform activation of the anomeric center with formation of a stable glycosyl donor having either an α- or β-structure; and (ii) that the second step should involve a catalyzed, sterically uniform, irreversible glycosyl transfer to the acceptor, proceeding with either retention or inversion at the anomeric center in high chemical yield and without affecting other bonds.

Apart from the direct acid activation (Scheme 1, path a) or acid-supported anomeric oxygen exchange for a leaving group (Scheme 1, path b), base-catalyzed transformation of the anomeric oxygen into a good leaving group (Scheme 1, path c) should be possible. Therefore, it is not surprising that 1-*O*-toluenesulfonylation has been known for a long time.[90] However, these compounds were prepared by reaction of the corresponding α-glycosyl halides with silver toluenesulfonate, providing predominantly α-toluenesulfonates; their use in glycoside synthesis could not gain any general importance even though several variations were investigated; for instance, introduction of electron-withdrawing *O*-protection to increase the $S_N2$ character of glycoside synthesis[1] or the use of a better leaving group.[1] The amounts of reagent and the difficult stereocontrol of both intermediate and product prevented a broader application of glycosyl sulfonates. Apparently the route *via* glycosyl halides and their activation with silver triflate[91] (see Section 1.2.3.2), demonstrating the close relation of these methods, is considerably more efficient.

Glycosyl transfer in nature takes place *via* glycosyl pyrophosphate or phosphate derivatives of nucleosides.[92] Surprisingly, only a few nonenzymic investigations with glycosyl phosphates have appeared.[93] The imitation of specific enzymatic processes in the laboratory requires an arsenal of enzymes which is not as yet available. However, interesting investigations with glycosyl transferases and also with glycosyl hydrolases have been reported.[94]

Studies on 1-*O*-activation with the Mitsunobu reagent have not attained general importance.[1]

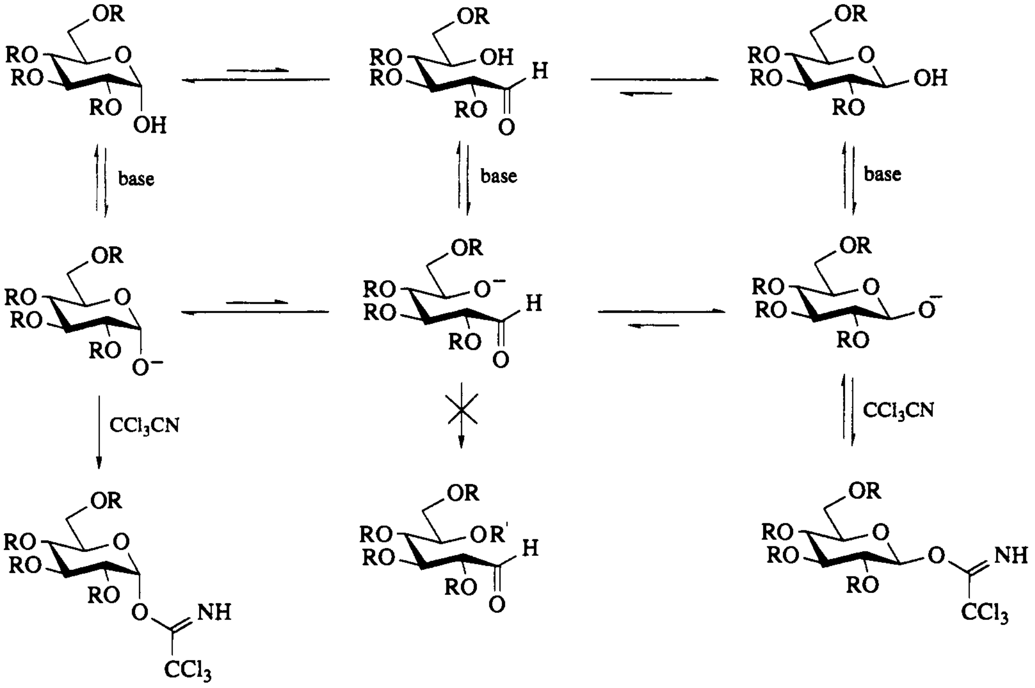
Activation of the anomeric oxygen by 1-*O*-acylation results in relatively low glycosyl donor properties. Therefore, either high temperatures in glycoside synthesis (carbonate activation[95]) or strong acidic catalysts are required. The acid lability of the sugar can be lowered by *O*- and *N*-acetylation, *O*-benzoylation and *N*-phthalimidoylation respectively, providing neighboring group active protective groups. This approach ultimately leads to the conditions of the Fischer–Helferich method (Scheme 1), which does not require a 1-*O*-activated intermediate but builds up the glycosyl donor potential solely by the action of strong acids. Thus the conversion of 1-*O*-acylated sugars into simple *O*-glycosides was successfully performed with the help of Lewis acids, for instance $ZnCl_2$, $SnCl_4$, $FeCl_3$, $BF_3{\cdot}OEt_2$ and $Ph_3CClO_4$.[1] In recent years the use of trimethylsilyl triflate as catalyst has afforded good results for *O*-[5,96] and *N*-glycoside[97] synthesis. The simplicity of the procedure offers valuable additions to glycoside and saccharide synthesis.

1-*O*-Silylation, for instance, providing 1-*O*-trimethylsilyl glycosides from 1-*O*-unprotected sugars in an anomerically pure form, has been shown by Tietze and coworkers to be useful in phenyl glycoside and 1,1′-diacetal (see Section 1.2.5) synthesis with *O*-silylated acceptors[98] and trimethylsilyl triflate as catalyst. The diastereoselectivity was dependent on *O*-protection.

The synthesis of orthoesters from 2-*O*-acylglycosyl halides and their mercury salt catalyzed rearrangement to glycosides and saccharides have been known for a long time.[5,9] The alkylating character, known for orthoesters especially under acidic conditions, generates the glycosyl donor properties. Thus, carboxylic acids furnish 1-*O*-acyl compounds.[99] The development of the orthoester method by Kochetkov and coworkers[100] has exhibited one major disadvantage, the formation of 2-*O*-unsubstituted sugars by a competing acid attack at the 2-*O*-atom. This side reaction could be overcome by formation of the acyloxonium intermediate and trapping it with cyanide or with an alkylthio group. Then *O*-trityl sugars as acceptors and trityl perchlorate or trityl tetrafluoroborate as coactivator result in good yields of 1,2-*trans*-linked disaccharides of glucose, galactose, mannose and rhamnose.[100]

### 1.2.4.2 The Trichloroacetimidate Method:[1,2] Derivation of New Principles for Glycoside Synthesis; Trichloroacetimidate Formation

The anomeric oxygen activations described above could not fulfill the requirements put forward. Either they failed to provide both activated intermediates or both anomeric glycosides were not obtained. Obviously, for a stereocontrolled activation of the anomeric oxygen, the anomerisation of the 1-OH, or the 1-O⁻, group in the presence of base has to be taken into account (Scheme 16). Thus, in a reversible activation process and with the help of kinetic and thermodynamic reaction control both activated anomers should eventually be obtainable.



Scheme 16

These considerations suggested that pyranoses and furanoses should undergo base-catalyzed addition directly and in a stereocontrolled manner to suitable triple bond systems A≡B (or compounds containing cumulative double bond systems A=B=C, Scheme 1, path c). Only instability of aldehydic intermediates in basic media and insufficient or undifferentiated reactivities of the α- and β-alkoxides seemed to lower the expectations for a stereocontrolled anomeric *O*-activation.

The formation of stable *O*-activated intermediates can be promoted by independent catalysis of the activation and glycosylation steps. Thus, after basic activation and trapping of the *O*-activated intermediates (first step), mild acid treatment, leading to irreversible acetal formation (second step), remains as the simplest form of catalysis for the glycosylation. The stable intermediates thus obtained in the first step should, by appropriate choice of the centers A and B (or A, B and C), have good glycosyl donor properties in the presence of acid. The water liberated in the glycoside formation is transferred, in two separate steps, to the activating agent A≡B (or A=B=C), thus providing the driving force for the reaction. This concept should fulfill the requirements given above for a good glycoside or saccharide synthesis, as demonstrated by the trichloroacetimidate method.

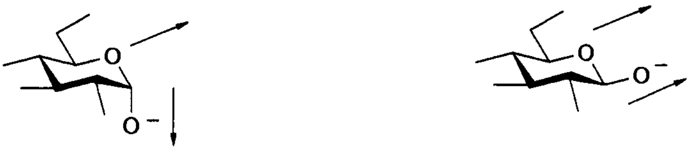
Electron deficient nitriles such as trichloroacetonitrile (A≡B; A = N, B = $CCl_3$) are known to undergo direct and reversible base-catalyzed addition of alcohols to give *O*-alkyl trichloroacetimidates.[1] This imidate synthesis has the advantage that the free imidates can be isolated as stable adducts, which are less sensitive to hydrolysis than their salts.

A detailed study of trichloroacetonitrile addition to 2,3,4,6-tetra-*O*-benzyl-D-glucose showed[1,101] that from the 1-oxide the β-trichloroacetimidate is formed preferentially or even exclusively in a very rapid and reversible addition reaction (Scheme 16). However, this product anomerizes in a slow, base-catalyzed reaction (*via* retroreaction, 1-oxide anomerization and renewed addition) practically completely to the α-trichloroacetimidate, with the electron-withdrawing 1-substituent in an axial position as favored by the thermodynamically efficient anomeric effect.[101,102] Thus with different bases, for instance $K_2CO_3$ and

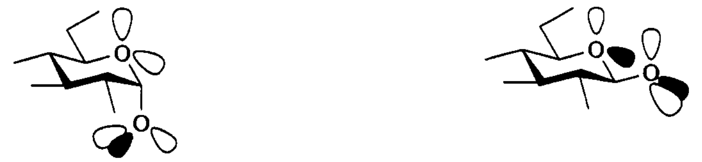
NaH, both anomers can be isolated in pure form and high yield *via* kinetic and thermodynamic reaction control. Both anomers are thermally stable and can be stored easily.

The higher nucleophilicity of the β-oxide can be attributed to a steric effect in combination with a kinetically effective stereoelectronic effect, resulting from repulsions of lone electron pairs or from dipole effects (Scheme 17).[101,102] This effect should be more pronounced in β-pyranosyl oxides than in β-pyranosides due to differences in oxygen lone pair orbitals. In addition, this kinetic anomeric effect should be particularly efficient in the β-mannopyranosyl oxide where the thermodynamic anomeric effect, favoring the α-anomer, is also stronger. This is confirmed in anomeric *O*-alkylation (see Section 1.2.5).

(a) Dipole–dipole interaction



(b) Lone-pair–orbital interaction



**Scheme 17** Enhanced nucleophilicity of β-oxides (kinetic anomeric effect)

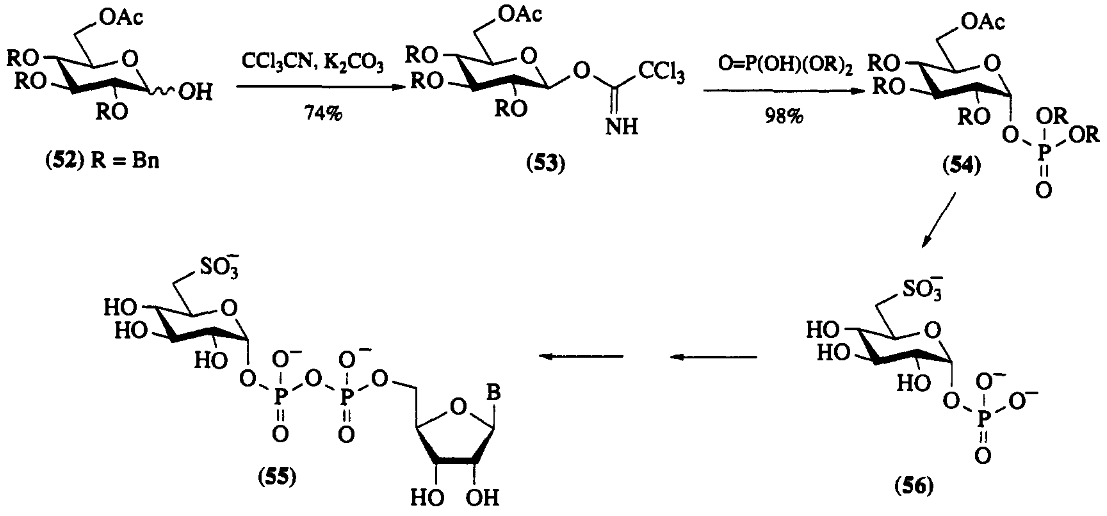
The stereoselective anomeric *O*-activation of carbohydrates and their derivatives through the formation of *O*-glycosyl trichloroacetimidates is applicable to all important *O*-protected hexopyranoses (Glc, Gal, Man, Fuc, Rha, GlcN, GalN), hexofuranoses, pentopyranoses and pentofuranoses, as well as to glucuronic acid, galacturonic acid and muramic acid, commonly providing stable compounds in a stereocontrolled manner. Thus the requirement for the first step, generation of an appropriate glycosyl donor, is fulfilled.

### 1.2.4.3 The Trichloroacetimidate Method: Application to Glycoside and Saccharide Synthesis

Ultimately, the significance of the *O*-glycosyl trichloroacetimidates is derived solely from their glycosylation potential under acidic catalysis. This potential has indeed been confirmed in various laboratories.[1,10–12,82,103–110]

The direct glycosylation of Brønsted acids is a particularly advantageous property of these new glycosyl donors.[1] Carboxylic acids usually react with inversion of configuration at the anomeric center to give *O*-acyl compounds without addition of any catalyst. The uncatalyzed glycosyl transfer from *O*-glycosyl trichloroacetimidates to phosphoric acid mono- and di-esters opens a simple route to glycosyl phosphates and glycophospholipids,[111] which are of interest as intermediates in biological glycosyl transfer and as constituents of cell membranes. Thus, from trichloroacetimidate (**53**; Scheme 18) the glycosyl phosphate (**54**) was obtained[112] and transformed *via* (**56**) into (**55**), which is an important intermediate in plant sulfolipid formation.[113] The anomeric configuration of the phosphate products obtained is determined by the acidity of the phosphoric acids applied; weak acids provide the inversion products, stronger acids lead directly to the thermodynamically more stable anomer. Phosphonates and phosphinates can be obtained similarly.[114]

Alcohol components for reaction as glycosyl acceptors generally require the presence of an acidic catalyst.[1] Boron trifluoride etherate at −40 °C to room temperature in dichloromethane or dichloromethane/hexane as solvents has proved to be very suitable with regard to yield and diastereoselectivity. This is exemplified by many successful applications of this method, until now mainly to hexopyranoside synthesis.[1,2] With neighboring group participation of 2-*O*- or 2-*N*-protective groups the 1,2-*trans*-products were obtained; with the nonparticipating 2-*O*-benzyl protective group or with the 2-azido-2-deoxy group inversion of configuration at the anomeric center was found to be preferred. For 1,2-*cis*-products (α-hexopyranosides of Glc, Gal, GlcN, GalN, Man, Rha, Fuc) good results were obtained *via* inversion of



Scheme 18

configuration at the anomeric center or performing the reaction with diethyl ether as the solvent and trimethylsilyl triflate as the catalyst.[115]

Because of the great importance of glycoconjugates as cell wall constituents of bacteria and as cell membrane constituents of all vertebrates (essentially glycosphingolipids and glycoproteins), a few applications to their syntheses will be discussed.

Amongst cell wall constituents of bacteria the cell wall peptidoglycan (called murein) has become increasingly important.[116] This peptidoglycan chain has a β(1 → 4)-linked glycan chain consisting of alternating *N*-acetylglucosamine and *N*-acylmuramic acid units (Scheme 19), which are cross-linked by a peptide chain (*e.g.* by L-Ala-D-iso-Glu-*meso*-DAP-D-Ala and Gly). The resulting peptidoglycan network and fragments of it exhibit pronounced immunostimulatory and antitumor properties. Therefore, the

synthesis of partial structures is of interest. For the synthesis of the GlcNAc β(1 → 4) MurNAc disaccharide (Scheme 19),[117] based on the trichloroacetimidate method, the donor (**57**) and the acceptor (**58**) were treated with an acidic catalyst. However, as indicated in the table in Scheme 19, the result was very much dependent on the 6-*O*-protection of the acceptor (**58**). Bulky groups, *e.g.* *t*-butyldimethylsilyl (TBDMS), or electron-withdrawing groups, *e.g.* benzoyl (Bz), did not improve the known low reactivity of the 4-OH group in glucosamine and derivatives. However, when a benzyl (Bn) group was introduced for 6-*O*-protection, the trichloroacetimidate method afforded in excellent yields and complete β-selectivity the desired disaccharides (**59**). Application of standard deprotection procedures resulted in the GlcNAc β(1 → 4) MurNAc disaccharide (**60**), which had already been synthesized *via* the Koenigs–Knorr procedure.[118]

The glycosphingolipids, being membrane constituents, possess a lipophilic ceramide (*N*-acylated sphingosine) moiety, which is part of the outer plasma membrane bilayer. The hydrophilic oligosaccharide moiety is therefore located on the outer membrane surface (see Section 1.2.1). After several investigations it became obvious that the best method for the glycosylation of these compounds proved to be the trichloroacetimidate method, which afforded better yields in glycosphingolipid syntheses than syntheses applying the Koenigs–Knorr method and variations of it.[119] This ceramide glycosylation procedure (Scheme 20) was recently also successfully applied by Ogawa and coworkers, for instance, to the synthesis of the $G_{M3}$ ganglioside and other tumor-associated antigens.[108] However, the yields are still not satisfactory, even though an improvement could be obtained by a sugar 2-*O*-pivaloyl group.[120] Therefore, based on a new sphingosine synthesis,[121] a versatile azidosphingosine glycosylation method was introduced by us[2,122] which was high yielding even in a recently performed *lactoneo*tetraosyl ceramide

synthesis.[123] This is also exhibited in the synthesis of cerebrosides (**64**) and (**65**) from *Tetragonia tetragonoides* possessing antiulcerogenic activity (Scheme 21).[124] The glucosylation with the *O*-acetylated trichloroacetimidate (**61**) to yield the intermediates (**62**) and (**63**) was β-specific.

### 1.2.4.4 The Trichloroacetimidate Method: Conclusions

The requirements for new glycosylation methods, outlined at the beginning, are practically completely fulfilled by the trichloroacetimidate method. This is indicated by the many examples and can be summarized as follows.

Features of the activation of the anomeric center are: (i) convenient base-catalyzed trichloroacetimidate formation; (ii) controlled access to α- or β-compounds by choice of the base; and (iii) thermal stability of α- and β-trichloroacetimidates up to room temperature (if required, silica gel chromatography can be performed).

Features of the glycosyl transfer are: (i) catalysis by acids (mainly Lewis acids) under very mild conditions; (ii) irreversible reaction; (iii) that other glycosidic bonds are not affected; (iv) usually high chemical yield (reactivity corresponds to the halogenose/silver triflate system); and (v) that stereocontrol of glycoside bond formation is mainly good to excellent: (a) participating protective groups give 1,2-*trans*-glycopyranosides, yielding β-glycosides of Glc, GlcN, Gal, GalN, Mur, Xyl, 2-deoxy-Glc and α-glycosides of Man, Rha; and (b) with nonparticipating protective groups, $BF_3 \cdot OEt_2$ as catalyst favors inversion of anomer configuration, yielding β-glycosides of Glc, GlcN, Gal, GalN, Xyl, Mur and GlcA, while TMSOTF as catalyst favors the thermodynamically more stable anomer, yielding α-glycosides of Glc, GlcN, Gal, GalN, Man, Fuc and Mur.

Besides the oxygen nucleophiles discussed here, nitrogen,[125] carbon,[126] halogen,[1,2] sulfur[127] and phosphorus nucleophiles[128] have also been used successfully as glycosyl acceptors for this reaction, illustrating in terms of stability, reactivity and general applicability the outstanding glycosyl donor properties of *O*-glycosyl trichloroacetimidates, which resemble in various aspects the natural nucleoside diphosphate sugar derivatives. Thus, the base-catalyzed *O*-glycosyl trichloroacetimidate formation has become a very competitive alternative to glycosyl halide and glycosyl sulfide formation.

### 1.2.4.5 Related Methods

The β-glycosyl imidates prepared by Sinay and coworkers[129] from α-glycosyl halides and *N*-substituted amides (particularly *N*-methylacetamide) using 3 equiv. of silver oxide have proven to be relatively unreactive in acid-catalyzed glycosidations.[5] The reactions proceed with inversion of configuration to form α-glycosidic linkages.[130] Neighboring group active protecting groups such as 2-*O*-acetyl lead to orthoester formation and not directly to the glycoside or saccharide.[130] The laborious synthesis of these imidates and their comparatively low reactivity have led to only a few special applications.[1,5]

Reactions with the Vilsmeier–Haack reagent,[1] with 2-fluoro-1-methylpyridinium tosylate[131] and with 2-chloro-3,5-dinitropyridine[131] for anomeric *O*-activation were investigated. The last reagent provided a glycosyl transfer method which is most closely related to the trichloroacetimidate method. However, routes for the specific preparation of the corresponding intermediates with the β-configuration have not been developed, and hydroxy groups that are difficult to glycosidate have not been studied to date. The isourea group, generated by carbodiimide reactions,[132] requires drastic conditions for reactions with glycosyl acceptors, limiting their usefulness.

## 1.2.5 THE ANOMERIC *O*-ALKYLATION METHOD[1,2]

The direct anomeric *O*-alkylation of furanoses and pyranoses with simple alkylating agents, for instance excess methyl iodide and dimethyl sulfate, has long been known.[1] Depending on the reaction conditions, either α- or β-glycosides are formed. A case of trehalose formation can be interpreted similarly.[1] Surprisingly, no studies to use this simple method in more complex glycoside and saccharide syntheses have been reported previously. At first direct anomeric *O*-alkylation (Scheme 1, path d) seemed very unlikely to fulfill all the requirements for a glycoside and saccharide synthesis. When all the remaining hydroxy groups are blocked by protecting groups, the ring–chain tautomerism between the two anomeric forms and the open-chain form (Scheme 17) already give three possible sites for attack of the alkylating agent. Thus the yield, the regioselectivity and the stereoselectivity of the direct anomeric *O*-alkylation

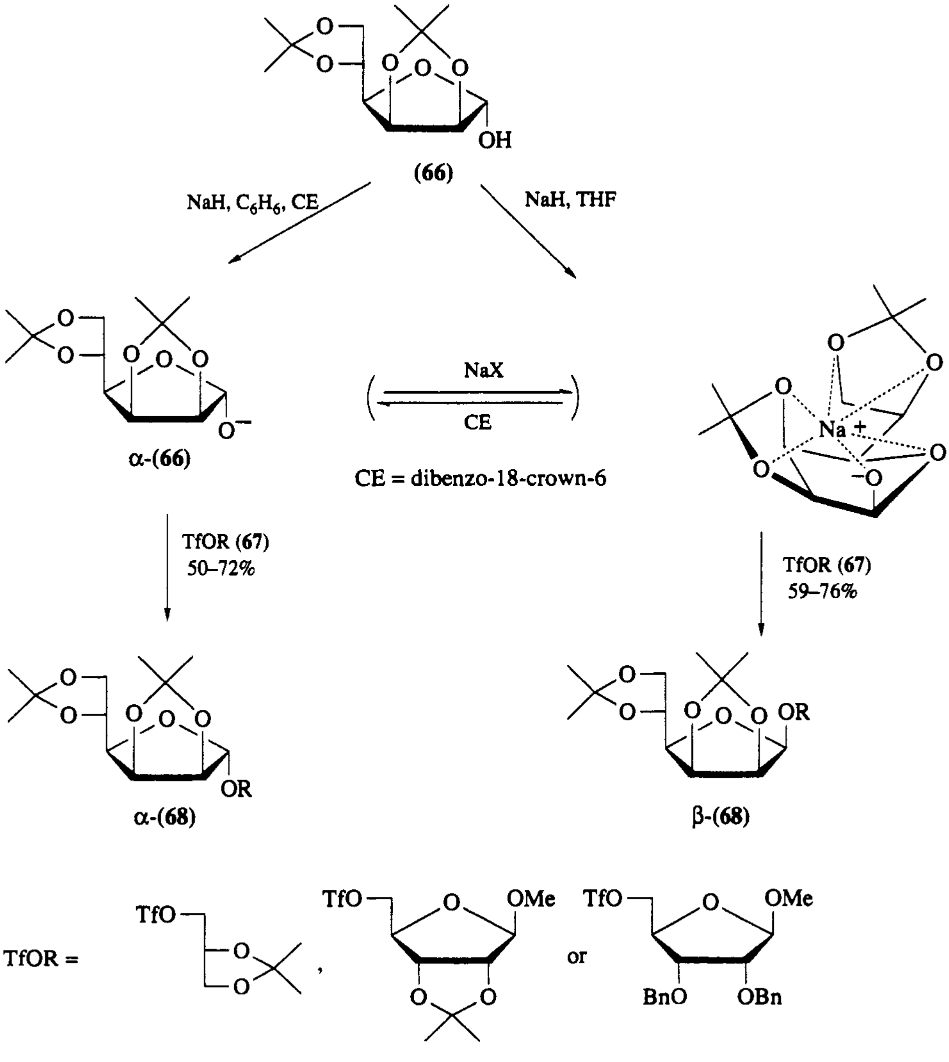
are governed by at least the following factors: (i) the stability of the deprotonated species; (ii) the ring–chain tautomeric equilibrium and its dynamics; and (iii) the relative reactivities of the three *O*-deprotonated species. Due to the irreversibility of the *O*-alkylation reaction, a kinetically regio- and stereo-controlled reaction course is required for selective product formation.

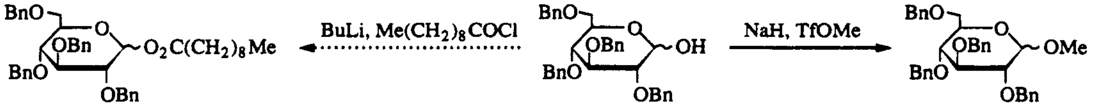
The first experiments with iodides revealed that better alkylating agents are required. Excellent reactivity was found for triflates providing, for instance with 2,3-*O*-isopropylidene-D-ribose and derivatives, depending on the reaction conditions, very high yields of α- and β-disaccharides respectively.[133]

Even partial *O*-protection was compatible with this reaction. The stereocontrol was effected by intramolecular metal–ion complexation. This could be substantiated by investigations on D-mannofuranose (**66**; Scheme 22).[134] Structure β-(**66**) shows that the β-oxide has practically ideal crown ether geometry, which probably stabilizes the β-configuration in less solvating media but decreases the reactivity.[134] Good β-selectivity with especially reactive electrophiles is thus to be expected under kinetic control. Accordingly, with the triflates (**67**) the β-D-mannofuranosides β-(**68**) were obtained almost exclusively. Furthermore, the expected influence of the reactivity of the electrophile on the anomeric ratio could be confirmed. If the intramolecular complexation is responsible for the high β-selectivity, more strongly solvating conditions should promote the α-selectivity. This was confirmed by the addition of an equimolar amount of crown ether. The alkylating agents then gave exclusively the corresponding α-D-mannofuranosides α-(**68**). Added sodium iodide had a competitive effect. Thus, for the furanoses studied, the stereocontrol results primarily from steric and chelate effects.



**Scheme 22**

2,3,4,6-Tetra-*O*-benzylglucose (Scheme 16) exists at room temperature in benzene or THF in an α:β anomeric ratio of ≈4:1.[135,136] This ratio is presumably not much changed on 1-*O*-deprotonation. However, when the acylation of the 1-*O*-lithiated species with decanoyl chloride is studied as a function of solvent and temperature, other relations are obtained (Figure 1).[135,138] Higher temperatures, especially in benzene, favor the β-product. Essentially the same result is obtained with the sodium salt and methyl triflate as alkylating agent.[138] The rate of α/β-anomerization and, due to the kinetic anomeric effect, the increased nucleophilicity of the β-oxide are responsible for this result. The addition of crown ether had no significant influence. Therefore, intramolecular complexation probably does not play a major role.[138]



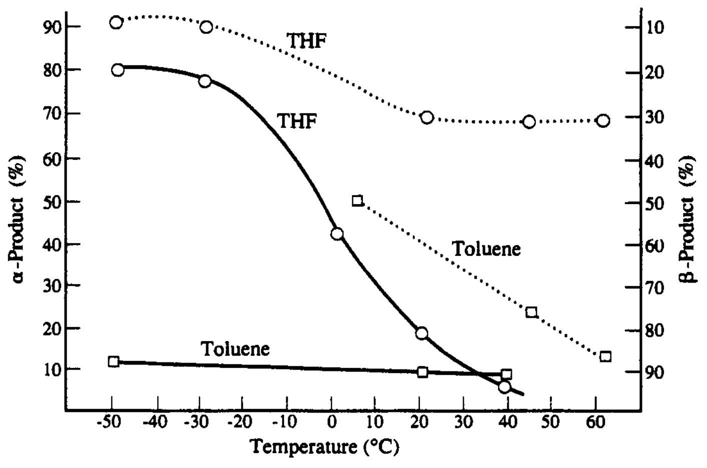


**Figure 1** Reaction of 2,3,4,6-tetra-*O*-benzyl-D-glucose in the presence of base with *n*-decanoyl chloride[135] (········) and with methyl triflate[138] (———) as a function of temperature and solvent

Thus, for instance, 2,3,4,6-tetra-*O*-benzyl-D-glucose, 6-*O*-unprotected 2,3,4-tri-*O*-benzyl-D-glucose and 2,3,4-tri-*O*-benzyl-D-galactose, 2,3,4,6-tetra-*O*-benzyl-D-mannose and 2,3,4-tri-*O*-benzyl-D-xylose were selectively transformed into the corresponding β-D-pyranosides, providing the corresponding glycosides and disaccharides in high yields. With bulky groups in the 6-*O*-position even α-selectivity could be reached in some cases.[1,2,133,134,137–139] Thus, the direct anomeric *O*-alkylation of sugars by primary triflates has become one of the most simple methods for stereocontrolled glycoside and saccharide synthesis. 1,1′-Diacetal formation has also been suggested to follow this reaction course.[1] However, further experiments are required to extend this method to high yield reactions with secondary triflates.[1]

The hydrophilic part of lipopolysaccharides consists of a complex oligosaccharide which is linked *via* KDO (3-deoxy-D-manno-2-octulosonate; α(2 → 6′)-connection) to a β(1 → 6)-linked glucosamine disaccharide.[7] The application of the Koenigs–Knorr method to generate this type of α-glycoside bond with KDO-halogenoses as donors has mainly led to unsatisfactory results due to hydrogen halide elimination and β-glycoside formation.[140] (Similar problems are encountered with neuraminic acid.) Better results were recently reported for fluoride as the leaving group.[141]

Base-catalyzed anomeric *O*-activation of KDO seemed to cause serious problems due to ring–chain tautomerism and due to the presence of the additional carboxylate group. However, for the application of the anomeric *O*-alkylation procedure solutions to these problems could be found.[142] The 4,5:7,8-di-*O*-cyclohexylidene derivative (**69**; Scheme 23) prefers the boat conformation providing, with the carboxamide group and the oxygens of C-5 and C-8, a tetradentate chelate ligand for the complexation of metal ions (Scheme 24). This complexation, generating dianionic species, offers high nucleophilic reactivity and α-diastereoselectivity, providing, with the 6-*O*-triflate of glucose (**70**) and glucosamine derivative (**71**), the desired α(1 → 6)-connected disaccharides (**72**) and (**73**) in good yield; they were transformed into compounds (**74**) and (**75**), respectively.

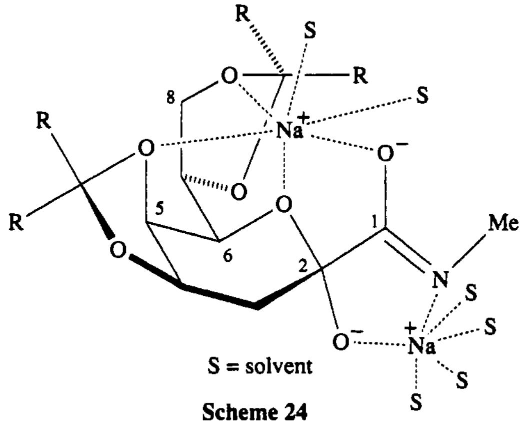
**Scheme 23**

In conclusion, the direct anomeric *O*-alkylation is an especially simple procedure for glycoside and saccharide synthesis, giving generally high yields and excellent diastereoselectivities, depending on intramolecular complexation, rate of anomerization and varying nucleophilicities of the α- and β-anomeric oxides. The limitation to primary alkylating agents will hopefully be overcome by different reaction conditions.



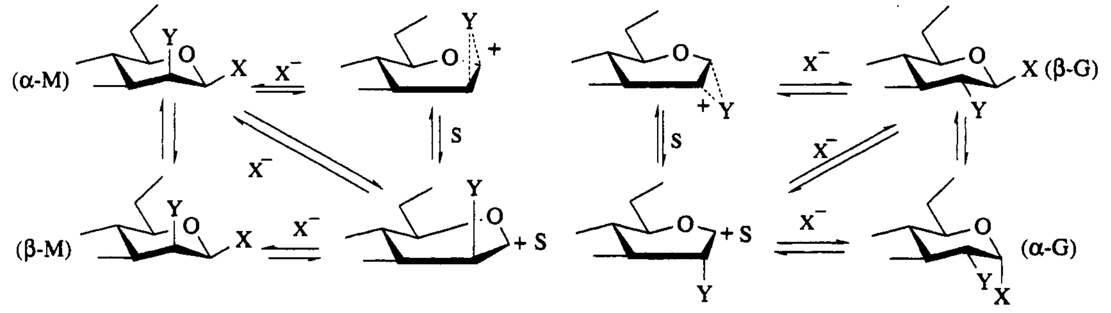
Scheme 24

## 1.2.6 SPECIAL METHODS

For acetal formation, besides the methods discussed thus far, further possibilities exist. For instance, oxidation/reduction methods could be envisaged. Thus, as described,[143] the acceptor can be oxidized to the acid. Anomeric *O*-acylation is a convenient process (see Section 1.2.4), requiring in the final step reduction of the acyloxy group to the alkoxy group, which could be performed in simple cases with borane. Similarly the donor could be oxidized to the lactone stage (and derivatives) and then acceptor addition and reduction would lead to the desired product. However, the efficiency of such methods has to be evaluated on the basis of the existing methodology.

## 1.2.7 GLYCOSIDES AND SACCHARIDES OF 2-DEOXY SUGARS

With 2-deoxy sugars, which lack an electron-withdrawing 2-substituent and also lack neighboring group participation, generally low stability of the glycosyl halides and low α/β-selectivity in glycoside and saccharide synthesis has been encountered. With modifications these statements are also true for KDO and neuraminic acid, which possess an electron-withdrawing caboxylate group at the anomeric position. (A detailed discussion of these two sugars met in glycoconjugates is beyond the scope of this chapter; for anomeric *O*-alkylation of KDO see Section 1.2.5.) Therefore a temporarily anchimerically assisting group was required in the 2-position, which is most readily introduced starting from glycals. This is demonstrated in Scheme 25 for a D-glucal derivative. $Y^+X^-$ addition can take place from the



Y = anchimerically assisting, removable group; X = leaving group or HOR' (acceptor); S = solvent

Scheme 25

β-site ($Y^+$) giving α,β-D-*manno* (M) configuration or from the α-site ($Y^+$) giving α,β-D-*gluco* (G) configuration. Neighboring group participation of the 2-substituent, Y, favors α-glycoside formation from the *manno* isomers and β-glycoside formation from the *gluco* isomers.

Several YX additions have been investigated. Reaction with iodine, silver salts and base in the presence of the glycosyl acceptor gave mainly the α-isomer.[144] The same result was obtained for *N*-bromosuccinimide,[145] *N*-iodosuccinimide (NIS)[146] and phenylselenyl chloride[147] in acetonitrile in the presence of the glycosyl acceptor. From these methods the NIS method, introduced by Thiem and coworkers,[146] has gained relatively wide use. Phenylsulfenate ester addition[148] gave varying *manno*:*gluco* addition ratios, resulting, after removal of the temporary phenylthio group, in α:β glycoside ratios from 1:1 to 1:4.

The recent addition of benzenesulfenyl chloride[149] to 3,4,6-tri-*O*-benzyl-D-glucal (**76**) resulted in practically complete *gluco* formation, providing easy access to the corresponding α-trichloroacetimidate (**77**; Scheme 26),[149] which turned out to be an exceptionally reactive glycosyl donor, even though the com-

pound is relatively stable. With various glycosyl acceptors the desired 2-deoxy-β-D-glucopyranosides (78–81) were obtained in high yields and with good β-selectivities at temperatures as low as –95 °C. Previous methods for 2-deoxy-β-glucopyranoside synthesis required the independent generation of 2-bromo-2-deoxy- or 2-deoxy-2-phenylthioglucopyranosyl halides.[150]

## ACKNOWLEDGEMENT

It is a great pleasure to acknowledge the contributions of my very capable collaborators, who developed some of the methods for glycoside synthesis described in this chapter. They are individually mentioned in the references. This work was supported by the Deutsche Forschungsgemeinschaft, the Fonds der Chemischen Industrie and the Bundesministerium für Forschung und Technologie.

I am grateful to Mrs. M. Crivellari and to Dr. K.-H. Jung for their help in preparing the manuscript.

## 1.3.1 INTRODUCTION

This chapter covers only the reactions of nitrogen nucleophiles with substrates having appropriate leaving groups and with epoxides and aziridines.[1] The reactions of electrophiles with the anion on the carbon atom adjacent to the nitrogen atom, have recently attracted attention in connection with asymmetric synthesis of chiral amines.[2a–2c] To keep this chapter to a reasonable length, however, this subject is not described. For the same reason, rearrangement reactions leading to amines and their derivatives are not included.[2d,2e]

## 1.3.2 ALKYLATION OF AMINES AND AMINE SYNTHONS

### 1.3.2.1 Alkylation of Amines by Alkyl Halides

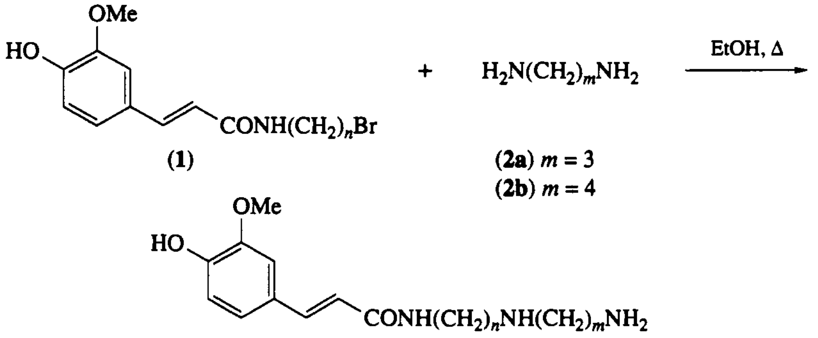
Alkylation of ammonia and another amine is, in principle, the most straightforward route to an amine. It is well known, however, that the value of this method in the laboratory is sometimes limited because of concomitant polyalkylation (Scheme 1).

For this reason, primary amines are generally prepared *via* azides or by the Gabriel synthesis and related procedures which will be described in Section 1.3.2.3. For the preparation of secondary amines, a

$$NH_3 + RX \longrightarrow RNH_2 + R_2NH + R_3N + R_4N^+X^-$$

**Scheme 1**

suitable excess of the amine component is generally used. Thus, the reaction of bromide (**1**) with an excess of 1,3- or 1,4-diamines (**2a**) and (**2b**) afforded the expected polyamine (**3a**) and (**3b**) (Scheme 2).[3]



(**1**)

(**2a**) $m = 3$
(**2b**) $m = 4$

(**3a**) $n = 4$, $m = 3$; 68%
(**3b**) $n = 3$, $m = 4$; 49%

**Scheme 2**

Onaka and coworkers have reported highly selective *N*-monoalkylation of aniline and its derivatives over alkali cation exchanged X- and Y-type zeolites. The intrinsic pore structures of X and Y zeolites are assumed to be responsible for the high selectivity. Linde 3A zeolites cannot promote the alkylation of aniline because of their smaller pore structure (Scheme 3).[4a] Aniline derivatives having strong electron-withdrawing substituents, such as *p*-nitroaniline, which is otherwise hardly alkylated even in the presence of KOH, can be successfully alkylated in benzene.[4b,4c] Celite coated with KF is also effective for the alkylation of amines.[5,6]

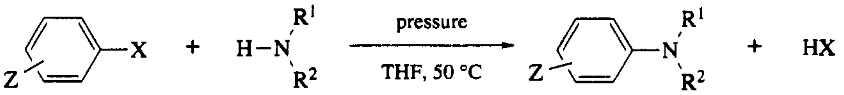
| 3A | (0.8%) | – |

**Scheme 3**

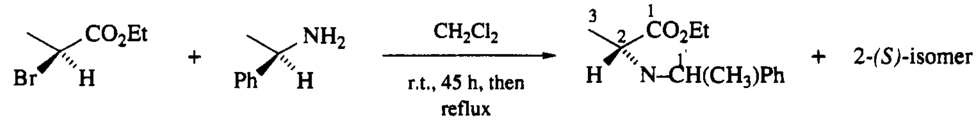
The use of phase-transfer catalysts in the presence of inorganic bases accelerates the alkylation of aromatic amines.[7] High pressure conditions have been used in the arylation of amines. Thus, no reaction took place between *p*-nitrochlorobenzene and acyclic aliphatic amines, such as $Bu^nNH_2$, $Bu^iNH_2$, $Bu^sNH_2$, $Bu^tNH_2$ and $Bu_2NH$ at 80 °C under 1 atm, while the corresponding secondary and tertiary aromatic amines were obtained under high pressures of 6–12 kbar (1 kbar = $10^5$ kPa) in THF at 50 °C for 20 h (Scheme 4). Cyclic amines (morpholine, piperidine and pyrrolidine) showed extremely high reactivity to give the corresponding *N*-*p*-nitrophenyl derivatives in quantitative yields under 6.0 kbar.[8]



X = Cl, Br, I; Z = *p*-$NO_2$, *o*-$NO_2$, *m*-$NO_2$, *p*-CN, *p*-Ac

**Scheme 4**

The amination of the α-carbon atom of carboxylic acid derivatives has been extensively studied by Effenberger and coworkers.[9] Ethyl (*S*)-α-bromopropionate reacted with (*R*)-1-phenylethylamine to give (2*R*,1′*R*)- and (2*S*,1′*R*)-*N*-(1′-phenylethyl)alanine ethyl ester, *e.g.* (2*R*,1′*R*)-(**4**) and (2*S*,1′*R*)-(**4**). Prolonged reaction time afforded the products in higher yields with decreasing stereospecificity (Scheme 5).

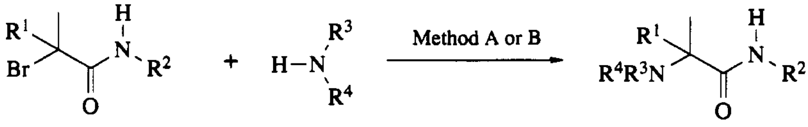


(2*R*,1′*R*)-(**4**) (2*S*,1′*R*)-(**4**)

| *Reflux* (h) (*Yield*, %) | (*2R,1′R*)-(*4*):(*2S,1′R*)-(*4*) |
|---|---|
| 48 (35) | 9:1 |
| 117 (60) | 7:1 |
| 248 (80) | 5:1 |

**Scheme 5**

α-Bromocarboxamide (**5a**) reacted with amines in the presence of NaH (method A) or phase-transfer catalysts (method B) to give α-aminocarboxamides (**6**). Sterically hindered amines, such as *t*-butylamine or diethylamine, can be successfully introduced. Nonionizable amide (**5b**) afforded only the corresponding acrylamide. In view of these results, zwitterions (**7a**) have been assumed as intermediates rather than aziridinones (**7b**; Scheme 6).[10]

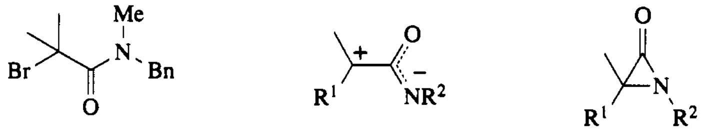


(**5a**) (**6**)

$R^1$ = Me, Et; $R^2$ = Bu$^t$, Bn, Ph

Method A: NaH, THF, 75 min, 66–88%

Method B: NaOH aq. (50%), $CH_2Cl_2$, Bu$^n{}_4$NBr, 4–10 h, 68–80%



(**5b**) (**7a**) (**7b**)

**Scheme 6**

α-Bromocarboxyhydrazides (**8**) reacted with amines to give the corresponding α-aminocarboxyhydrazides (**9**), which were converted into free acids by alkaline hydrolysis (Scheme 7). Intermediacy of aziridinone (**10**) has been assumed.[11]

Various methods for the synthesis of allylamines have been reported.[12–15] Reaction of allylic bromide (**11**) with amines gave $S_N2$ and $S_N2'$ substitution products in the ratio $S_N2$:$S_N2'$ ranging from *ca.* 1:20 for the reaction with piperidine to 9:1 for the reaction with diisopropylamine (Scheme 8).[12] The product distribution changes with a slight change in the electron-withdrawing capacity of the arenesulfonyl group, as well as the structure of the amines.

Functionalized β-amino-α,β-unsaturated lactones,[13a] esters[13b] and nitriles[13b] can be prepared by nucleophilic vinylic substitution of halogen atoms by amines on the corresponding β-halo-α,β-unsaturated compounds (**12**), (**13**) and (**15**) (Scheme 9). 3-Bromo-2-butenoates (*E*)-(**13**) and (*Z*)-(**13**) reacted with secondary amines to give (*E*)-β-aminopropenoates (*E*)-(**14**) regardless of the initial stereochemistry, while the reaction with primary amines yielded a mixture of (*E*)- and (*Z*)-(**14**), when $R^1$ = H, with the latter predominant. In contrast, the substitution of (*E*)- and (*Z*)-nitriles, (*E*)-(**15**) and (*Z*)-(**15**), with second-

ary amines proceeded with retention of original alkene configuration, whereas with primary amines (*E*)-isomers were formed as main products, *e.g.* (*E*):(*Z*) = 85:1 to 5:25. When the substitution was carried out with aziridine on the four substrates, (*E*)-(**13**), (*Z*)-(**13**), (*E*)-(**15**) and (*Z*)-(**15**), the reactions proceeded in every case with retention of configuration.[13b,c]

Intramolecular displacement of aliphatic amines having a suitable leaving group also affords cyclic amines. In order to avoid further alkylation, the amino function is protected by appropriate groups. The tosyl group has frequently been utilized to this end, where cyclization proceeds through an anionic displacement reaction.

The rate of cyclization varies with ring size. Kinetic studies of cyclization of a series of anions derived from *N*-tosyl-ω-bromoalkylamines, TsNH(CH$_2$)$_n$Br with $n$ = 2–6, in DMSO–H$_2$O (99:1) have revealed that the rates vary markedly with ring size in the order 5 > 3 > 6 > 7 > 4. First-order rate constants ($k_{intra}$) for cyclization have been translated into effective molarities (*EM*) with reference to the intermolecular alkylation ($k_{inter}$) of *N*-tosylbutylamine with butyl bromide (30-fold excess). The results are shown in Scheme 12.[17]

In the preparation of cyclic amines, especially large-membered and strained ones, the use of cesium salts of tosylamides exhibits enhanced reactivity (Scheme 13).[18] The solvent also plays an important role. Macrocyclization can also be successfully carried out under high pressure conditions.[19]

Dealkylation of tertiary amines and quaternary ammonium salts affords lower substituted amines. Reaction systems that can be utilized to cleave a C—N bond involve sodium amalgam (Emde degradation), $LiAlH_4$, $H_2$/Pd, sodium hydrogen telluride, cyanogen bromide (von Braun reaction) and acyl chlorides.[20] 1,1′-Binaphthyl substituted secondary and tertiary amines (**21**) and (**22**) were synthesized by double alkylation of primary or secondary amines with 2,2′-bis(bromomethyl)-1,1′-binaphthyl (**20**), followed by reduction (Scheme 14). Diaminated binaphthyls of type $(R'RNCH_2Ar)_2$ were never formed even when a very large excess of amine is present.[20a]

The reaction of amino alcohols, such as ephedrine or prolinol, with (**20**) took place at the nitrogen atom to give quaternary ammonium salts (**23**) and (**24**) (Scheme 14).[20a] The selective *N*-alkylation was again observed in the reaction of amino alcohol (**25**) with *N*-ethylchloroacetamide (2.05 equiv.) in MeCN in the presence of $Na_2CO_3$ under reflux. Subsequent reduction of the resulting diamide gave triamine (**26**; Scheme 15).[21a] Chlorohydrin (**27**) reacted with excess primary amines in the presence of $Na_2CO_3$ or $K_2CO_3$ to give secondary amines (**28**; Scheme 15).[21b] The chemoselectivity observed can be explained by higher nucleophilicity of the amino group than the hydroxy group; $Na_2CO_3$ as the base cannot remove the proton from the pendant hydroxy group.

When the hydroxy group of amino alcohol was converted into alkoxide, alkylation took place at the oxyanion in preference to the nitrogen atom. Thus, the sodium alkoxide derivative of (**28**) reacted with polyethylene glycol ditosylate or dichloride (**29a–29c**) to give the corresponding aminomethyl crown ethers (**30**).[21b] Chiral amino alcohols (**31**) can be converted into amino ethers (**32**) *via* alkoxides.[22] In contrast, treatment of *N*-tosylamino alcohol (**33**) with NaH, followed by reaction with a fivefold excess of 1,2-dibromoethane afforded (**34**; Scheme 16).[23a]

### 1.3.2.2 Alkylation of Amines by Sulfonates and Other Activated Alcohols

Alcohols are readily available in a variety of cyclic and acyclic forms, chain lengths and sense of chirality. Therefore, alcohols have been utilized as versatile starting materials in organic synthesis. In order to prepare amines from alcohols by substitution reactions, the hydroxy group must be converted into a leaving group appropriate to subsequent displacement with nitrogen nucleophiles. Although halogenation is often utilized to this end, introduction of suitable activating groups may be more convenient for the conversion of an alcohol into an alkylating reagent. Of a variety of activated alcohols described in Section 1.2.5, sulfonates are most frequently utilized in the preparation of amines.

A systematic study of the substitution reactions of chiral ethyl propionate derivatives having a leaving group at the α-position (**39a**–**39e**) with amines reveals that nucleofugacity of the leaving group decreases in the order TfO >> Br > MsO > TsO > Cl and that decreasing reactivity causes increasing racemization and elimination as a consequence of the drastic conditions that are required (Scheme 18 and Table 1). As described in the previous section (Scheme 5), the reaction of (**39d**) with (*R*)-1-phenylethylamine accompanied considerable racemization.[9,24]

**Scheme 19**

The displacement of sulfonates with amines or azide ion generally proceeds with inversion of the configuration at the secondary methanol center. As an alkylating reagent, sulfonates are, in general, superior to the corresponding halides. For instance, the alkylation of *p*-toluidine with 2-*t*-butyl-1,3-bis(tosyloxy)propane (**44a**) afforded azetidine (**45**) in 35% yield, while dichloride (**44b**) afforded a lower yield of (**45**) due mainly to competitive elimination (Scheme 20).[26] Dibromides (**46**) and (**47**) reacted with *p*-toluidine giving the corresponding azetidine in 75% and 14% yields, respectively. The reactions shown in Schemes 14 and 20 suggest that the yields of cyclic amines formed by the reaction of bifunctional alkylating reagents with amines are influenced not only by leaving group but also by substitution patterns of the substrates.

**Scheme 22**

Monosulfonation of primary and secondary diols can generally be accomplished under controlled conditions.[29] The selective tosylation of diol (**54**), followed by reaction with trimethylamine in a sealed tube and ion exchange with Dowex-1(Cl$^-$) resin gave (+)-muscarine chloride (**55**; Scheme 23).[30] Intramolecular alkylation of cyclic amine (**56**) gave quaternary ammonium salt (**57**); subsequent hydrogenolysis of the benzyl group in (**57**) afforded (**58**; Scheme 23).[31]

Activated alcohols other than sulfonates can also be utilized in the alkylation of amines. For example, *O*-methyl-*N*,*N'*-dicyclohexylisourea reacted with 4-dimethylaminobutanoic acid to give ammonium salt (**59**; Scheme 24).[32,33] *O*-Alkylisourea can also be used in the alkylation of imides.[34a]

2-Oxazolines (**60**) reacted with secondary amines in the presence of a catalyst to give *N*-(2-aminoethyl)carboxamides (**61**), which were hydrolyzed to unsymmetrically substituted diaminoethanes (**62**). Although reaction conditions are drastic, the yields of products are high (Scheme 24).[34b]

Alkoxyphosphonium salts can also be utilized in the alkylation of amines,[35] where methods of generation of the phosphonium salts are crucial. The reaction of aminophosphonium reagent (**63**) with alkoxides in the presence of amines to be alkylated (80 °C, 1 h in DMF for secondary amines and in benzene for primary amines) afforded the corresponding higher substituted amines in good to excellent yield. Phosphonium amide (**64**) has been proposed as a key intermediate (Scheme 25).[36] Various amines and azides have been prepared by the use of alkoxy[tris(dimethylamino)]phosphonium salts (**65**).[35a]

Reagents formed by combining $Ph_3P$ with $CCl_4$ and with diethyl azodicarboxylate (DEAD) promote cyclization of amino alcohols to cyclic amines (Scheme 26).[37,38] Various 2-amino alcohols reacted with diethoxytriphenylphosphorane (**66**) to afford the corresponding aziridines in 85–90% yields. The reaction proceeds with retention of the configuration at the amino carbon (C-2) (Scheme 26).[39] In view of

## 1.3.2.3 Manipulation of Amino Group Equivalents

### *1.3.2.3.1 Alkylation of azide ion*

Azide anion, which is more nucleophilic than amines, reacts with alkyl halides and activated alcohols giving the corresponding alkyl azides. Phase-transfer conditions can also be utilized.[40] For details, readers are referred to a comprehensive review.[41] Alkyl azides thus formed can be readily transformed into primary amines by a variety of reagents or reaction systems which involve catalytic hydrogenation,[40–42] $LiAlH_4$,[43] $NaBH_4$ under phase-transfer conditions,[44a] $NaBH_4/THF/MeOH$,[44b] $Ph_3P$ or $(RO)_3P/H_2O$,[45] $H_2S/Py$,[46] $Pd–C/HCO_2NH_4/MeOH$,[47] NaTeH,[48] nickel boride[49] and $SnCl_2/MeOH$.[50]

The reduction system must be chosen by taking into account the substitution pattern of substrates. For example, azide (**67**) was converted into the amine (**68**) by treatment with $SnCl_2$ in MeOH (64% yield), whereas catalytic hydrogenation or $LiAlH_4$ reduction could not be used due to loss of the 5-bromo group.[51] Azide (**69**) was converted into piperidine (**70**) by the reaction with $Ph_3P$ in $CHCl_3/H_2O$ in 61% yield (Scheme 27).[52] The reaction of azides with $PPh_3$ gives iminophosphoranes (Staudinger reaction), hydrolysis of which affords primary amines. The procedure has an advantage because the initially formed iminophosphoranes can also be utilized as key intermediates for various nitrogen compounds, such as secondary amines, aziridines, amides, imines, nitro compounds and aminophosphonium salts.[53] Nickel boride generated *in situ* from $NaBH_4$ and nickel chloride does not reduce a ketone, ester, epoxide or a double bond.[49] Sodium hydrogen telluride is inert to unconjugated carbon–carbon double and triple bonds, unconjugated carbonyl, carboxyl, amide, ester, cyano and sulfone groups.[48]

**Scheme 29**

Since the reaction of alkylating reagents with azide ion generally proceeds through an $S_N2$ process, inversion of the reaction center takes place. Thus, for the synthesis of amines with a definite configuration at the carbon atom to which the amino group is attached, the preparation of enantiometrically pure alkylating reagent is a prerequisite.

Chiral α-halo esters (**72a**) and (**72b**) and α-halo imide (**72c**) have been prepared in high diastereomeric purity by the use of Oppolzer's chiral auxiliary (**71a**) and (**71b**) and Evans' chiral auxiliary (**71c**), respectively. The reactions of (**72a**), (**72b**) and (**72c**) with azide ion proceeded with inversion of configuration (Scheme 30).[55,56] In the latter reaction, the use of NaN$_3$ (DMF or DMSO, 0 °C) has been reported to afford 2–5% epimerization.[56] The azides thus prepared were transformed into the corresponding amino acids with high chemical and optical yields.

Reaction of chiral boronates (**73**) with (dihalomethyl)lithium afforded (1*S*)-1-haloboronate (**74**), which was converted into (1*R*)-1-azidoboronate (**75**). Homologation of (**75**) with (dichloromethyl)lithium to 1-chloro-2-azidoboronate, oxidation to azido acid and catalytic hydrogenation afforded (–)-amino acids in 32–63% overall yields with 92–96% *ee* (Scheme 31).[57] The procedure has also been applied to the preparation of a chiral *vic*-amino alcohol.[58]

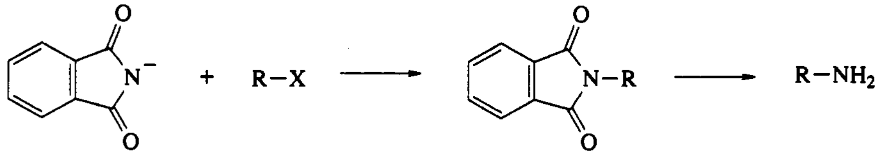
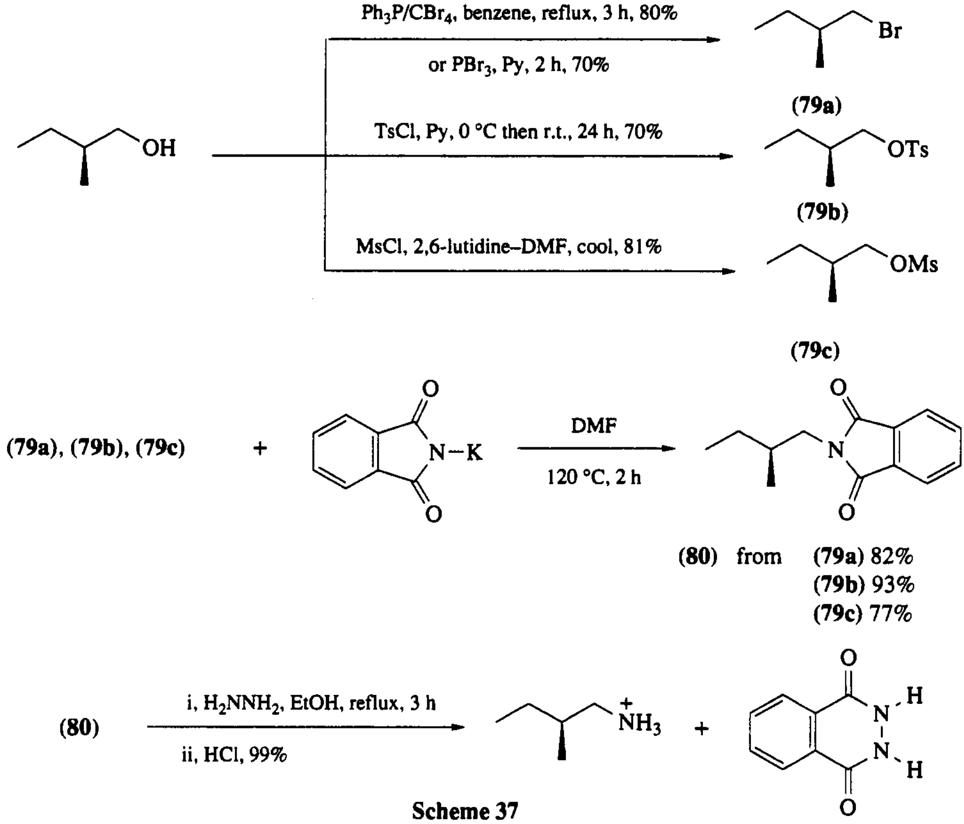
### *1.3.2.3.2 Gabriel synthesis*

The Gabriel synthesis is a classical but still useful procedure for the preparation of primary amines. The method consists of alkylation of phthalimide anion with an appropriate alkylating reagent and subsequent removal of the phthaloyl group to generate primary amines (Scheme 36).[65]



Scheme 36

Alkyl halides and alkyl sulfonates have been generally used as alkylating reagents. An example of the conversion of an alcohol into a primary amine by the Gabriel synthesis is shown in Scheme 37.[66]



Scheme 37

Alkylation of phthalimide anion can be carried out under solid–liquid phase-transfer conditions, using phosphonium salts[67] or ammonium salts.[68] In the reaction systems using hexadecyltributylphosphonium bromide, alkyl bromides and alkyl methanesulfonate are more reactive than alkyl chlorides. Octyl iodide is less reactive than the corresponding bromide and chloride.[67] (*R*)-2-Octyl methanesulfonate was converted into (*S*)-2-octylamine with 92.5% inversion.[67] Kinetic resolution of racemic ethyl 2-bromopropionate by the use of a chiral quaternary ammonium salt catalyst has been reported.[68] Under liquid–liquid phase-transfer conditions, *N*-alkylation of phthalimide has been reported to give poor results.[68b]

In the presence of [2.2.2]cryptand, the reaction of potassium phthalimide with alkyl halides proceeded smoothly in THF or benzene even at room temperature to give the corresponding *N*-alkylphthalimides in good to excellent yields.[69]

The alkylation of phthalimide can also be accomplished with *O*-alkylisoureas and alkoxyphosphonium salts. Thus, the reaction of *O*-alkyl-*N*,*N*′-cyclohexylisourea with phthalimide afforded *N*-alkylphthalimides in 60–70% yields (DMF, 120 °C, 2–24 h). Starting from (*R*)-2-octylisourea, (*S*)-2-octylamine was obtained in 97.6% *ee*, indicating 98% inversion of the configuration took place.[34a]

The reactions involving alkoxyphosphonium salts are also effective for the *N*-alkylation of phthalimide with virtually complete inversion of the secondary methanol center.[35,61] Thus, the reaction of (*S*)-alcohol (**81**) with phthalimide, DEAD and triphenylphosphine afforded (**82**), which was subjected to a sequence of reactions to yield (2*R*,5*R*)-diamine (**83**) and the (2*R*,5*S*)-isomer in a ratio of 99.4:0.6.[70] The secondary methanol center of alcohol (**84**) was again inverted in the reaction with phthalimide, DEAD and triphenylphosphine giving (**85**).[71] In contrast, alcohol (**86**) afforded *syn*- and *anti*-phthalimide derivatives (**87**) and (**88**) in a ratio of 1:1 under similar conditions (Scheme 38).[72] This result would be explained by assuming intermediacy of a carbonium ion, which is stabilized by an adjacent *p*-methoxyphenyl group.

### *1.3.2.3.3 Modified Gabriel synthesis*

Although alkylation of phthalimide can now be performed under mild conditions as described in the preceding section, the final deprotection step still requires somewhat drastic conditions, *e.g.* the use of strong acid or base, or, alternatively, hydrazinolysis, at elevated temperature, due to the inherent stability of the phthaloyl group.[65] This has prompted investigation of a number of alternatives to phthalimide which afford *N*-alkyl derivatives amenable to milder deprotection.

Methyl *t*-butyl iminodicarboxylate (**91**) and di-*t*-butyl iminodicarboxylate (**93**) have been used in a modified Gabriel synthesis.[74–76] Thus, the potassium salt of (**91**) reacted with alkyl halides to give the corresponding *N*-alkylated products (**92**) in 59–95% yields (in DMF or DMSO, 20–60 °C) except for alkylating reagents susceptible to base-catalyzed side reactions. Under basic conditions, (**92**) gave *N*-*t*-butoxycarbonylamines, whereas, with trifluoroacetic acid, *N*-methoxycarbonylamines were obtained (Scheme 40).[74]

The potassium salt of (**93**) reacted with allylic bromides (**94**) to afford protected amines (**95**). Hydrogenolysis of (**95a**), followed by successive treatment with HBr–AcOH and ion exchange resin gave amino alcohol (**96**). Treatment of (**95a**) with HBr–AcOH gave allylamine (**97**; Scheme 40).[76]

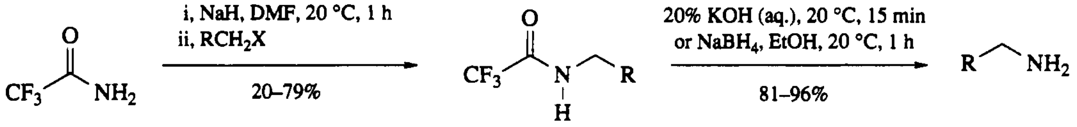
**Scheme 41**

Alkylation of (**98**) can also be carried out by reaction with alcohols in the presence of DEAD and triphenylphosphine at room temperature. The yields of crude (**99**) were in the range 80–90% for primary alcohols and 70–75% for secondary alcohols with nearly complete inversion of the secondary methanol center.[77b]

Sulfonyl groups can also be utilized to reduce the basicity of amino functions. Inter- and intra-molecular cyclization using bifunctional tosylamides have been widely utilized in the preparation of macrocyclic polyamines (Scheme 13). Trifluoromethanesulfonamide and its derivatives can also be used in the preparation of primary and secondary amines.[78]

In contrast to the anion of diethyl phosphoramidate or trifluoromethanesulfonamide, which cannot be cleanly monoalkylated,[77,78] the anion of trifluoroacetamide (**100**) was monoalkylated by alkyl halides or alkyl methanesulfonate. The resulting *N*-alkylamides (**101**) were converted into primary amines by alkaline hydrolysis or reduction (NaBH4; Scheme 42). Various primary amines were prepared from (**100**) with primary alkyl iodides or methanesulfonate, benzyl and allyl halides, α-bromocarbonyl compounds and 2,4-dinitrochlorobenzene. However, competitive elimination is a serious side reaction for less reactive primary alkyl chlorides and secondary halides or methanesulfonate. The synthesis of secondary amines from (**100**) has also been reported.[79]

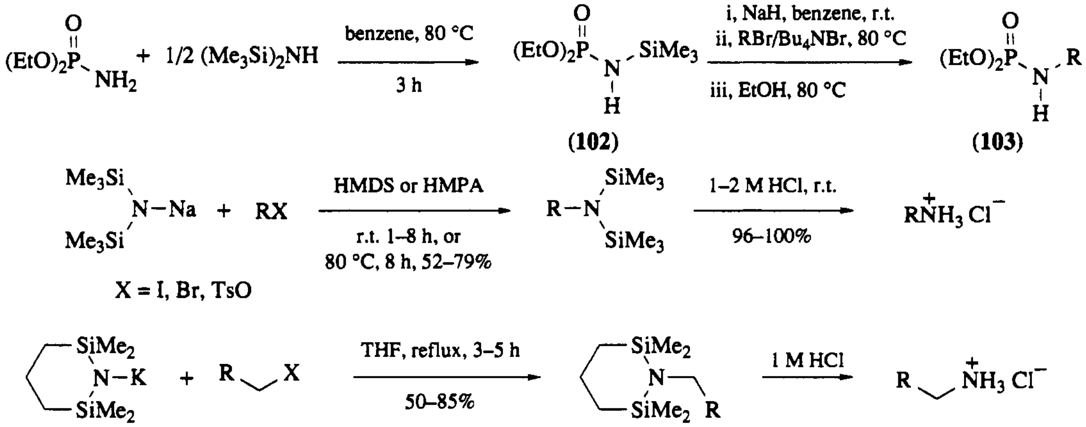


(**100**) (**101**)

**Scheme 42**

### 1.3.2.3.4 *Alkylation of amine synthons having a nitrogen–heteroatom bond*

One of the two hydrogen atoms of phosphoramidates can be temporarily blocked with a trimethylsilyl group. The sodium salt of diethyl *N*-(trimethylsilyl)phosphoramidate (**102**) reacted with alkyl bromides in benzene in the presence of 10 mol % of tetra-*n*-butylammonium bromide to afford, after desilylation, the corresponding *N*-alkyl derivatives (**103**) in 79–95% yields for primary alkyl halides. Secondary alkyl halides gave poor results (Scheme 43). The addition of the quaternary ammonium salt is essential to promote the alkylation reaction.[80] Hexamethyldisilazane and its cyclic analogs can also be utilized in the preparation of amines under moderate conditions (Scheme 43).[81,82]



(**102**) (**103**)

**Scheme 43**

The utility of sulfenimides has been demonstrated.[83] The procedure has the particular advantage of using practically neutral conditions for the final deblocking step (Scheme 44).

*N*-Alkylation of benzylhydroxylamine by a primary alkyl bromide proceeded smoothly at room temperature. HMPA is the solvent of choice and addition of tetraethylammonium iodide facilitates the reaction. Dehydration of the resulting *N*-alkylhydroxylamines and subsequent acid hydrolysis gave the corresponding primary amines (Scheme 45).[84]

Alkylation of imino or amidine nitrogen and subsequent hydrolysis give rise to amines. For instance, alkylation of imine esters (**104a**) or amidine esters (**104b**) with dimethyl sulfate or methyl triflate, fol-

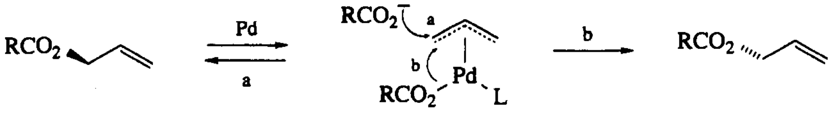
### 1.3.3 REACTION OF π-ALLYL COMPLEXES WITH NITROGEN NUCLEOPHILES

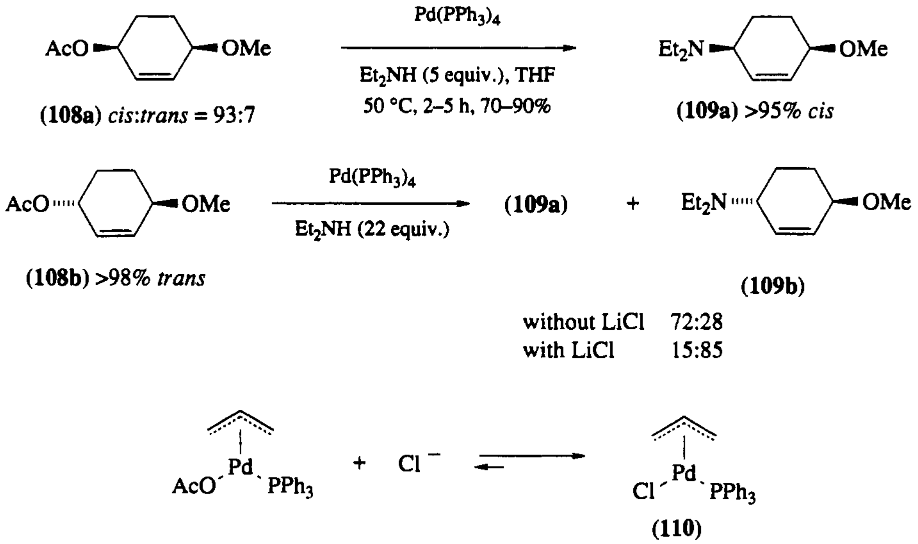
Palladium-catalyzed nucleophilic substitution reactions of allylic substrates have become useful in organic synthesis.[88] As allylic substrates, allyl alcohols, halides, carboxylates, phosphates or vinyl epoxides can be utilized.

Although nucleophiles generally substitute allylic leaving groups with retention of configuration, the substitution of allylic carboxylates sometimes proceeds in a nonstereospecific manner due to palladium-catalyzed isomerization of the substrates (Scheme 48).[89]



Scheme 48

This drawback has been overcome by the use of polymer-supported palladium catalysts.[90] Addition of LiCl also provides remarkably enhanced selectivity without affecting the reaction rate.[89] Thus, the reaction of *cis*-acetate (**108a**) reacted with diethylamine in the presence of $Pd(PPh_3)_4$ to give *cis*-amine (**109a**) in good yield, whereas *trans*-acetate (**108b**) afforded (**109a**) and *trans*-amine (**109b**) with the former predominant. However, the addition of LiCl in the reaction system resulted in the formation of (**109b**) as the main product (Scheme 49).[89] The observed effect of LiCl on the stereochemistry of the reaction has been attributed to the formation of intermediate (**110**), where chloride blocks the coordination of acetate (Scheme 49).[89]



Scheme 49

The reaction of (*E*)-(*syn*)-2-acetoxy-5-chloro-3-hexene, *syn*-(**111**), with diethylamine in the presence of a palladium catalyst gave (*E*)-(*syn*)-2-acetoxy-5-(dimethylamino)-3-hexene, *syn*-(**112**). In contrast, the reaction of *syn*-(**111**) with diethylamine under $S_N2$ conditions afforded the *anti* isomer, (*anti*-(**112**); Scheme 50).[91]

The fugacity of the leaving groups at allylic positions is demonstrated to be in the order $—OPO(OEt)_2$ > —OAc > —OH and —Cl > —OAc > —OH.[92–94] Therefore, chemoselective stepwise substitution of differentially substituted bifunctional allylic substrates is possible as depicted in Scheme 51.[92,94] In the

Although a variety of primary and secondary amines can be utilized as nitrogen nucleophiles, amination of allylic substrates with ammonia has been reported to be unsuccessful. Therefore, bis(*p*-methoxyphenyl)methylamine,[95] sodium *p*-toluenesulfonamide[96] or sodium azide[97] have been utilized instead of ammonia. In the presence of a palladium catalyst, imides, such as phthalimide, react with allylic esters with the exception of geranyl and linalyl acetates. *O*-Geranyl- and *O*-linalyl-isourea derivatives, however, reacted with phthalimide giving the expected *N*-allylic phthalimides in 65% and 71% yields, respectively.[98]

The intermolecular reaction described above has been extended to intramolecular displacement leading to cyclic amines.[99] Reaction of allylic alcohols with morpholine in the presence of a nickel catalyst has also been reported.[100]

In the presence of a palladium catalyst, allyl epoxides (**113**) react with nitrogen nucleophiles at the alkenic carbon atom remote from the oxirane ring to give 1,4-adducts (**114**).[101] In the absence of a palladium catalyst, azide ion attacks the oxirane ring affording 1,2-adducts (**115**; Scheme 52 and Table 2).[101b] Vinyl epoxide (**116**) gave 1,2- and 1,4-azido alcohol in a ratio of 1:1.5 irrespective of the reaction system.[101b] Intramolecular cyclization of vinyl epoxide (**117**) in the presence of a palladium catalyst afforded isoquinuclidine (118; Scheme 52).[101c]

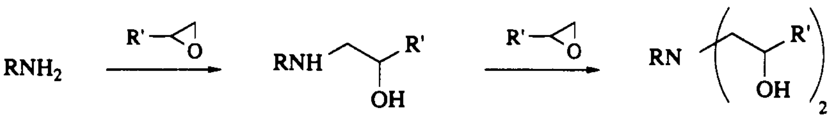
## 1.3.4 RING OPENING OF SMALL RING HETEROCYCLES BY NUCLEOPHILES

### 1.3.4.1 Epoxides

Reaction of epoxides with nitrogen nucleophiles affords a variety of β-hydroxyamines and their equivalents. Comprehensive review articles have been published.[105] In conjunction with the development of diastereoselective and enantioselective syntheses of epoxy alcohols, selective oxirane ring cleavage of 2,3-epoxy alcohols and carboxylates by nitrogen nucleophiles has become a versatile route to various amines and their equivalents. For details, the reader is referred to refs. 105c and 105d.

In the reaction with methyloxirane in $H_2O$ at 20 °C, the reactivity of the amines decreases in the order: piperazine > dimethylamine > pyrrolidine > piperidine > morpholine > diethylamine > di-*n*-butylamine > di-*n*-propylamine.[106] Under neutral or basic conditions, nucleophiles generally attack at the sterically less-hindered carbon atom of the oxirane ring.

The simplest method for the preparation of β-amino alcohols consists of heating an amine with an epoxide; limitations sometimes occur with poorly nucleophilic amines and with sensitive epoxides. Another limitation is that the first addition of an amine to an epoxide is often followed by one or more secondary additions (Scheme 55). Therefore, for a primary amine, an excess of the amine is used so that secondary reactions are reduced to a minimum. When a secondary amine is reacted with an epoxide, the product is a tertiary amine and the secondary reaction is insignificant.[106,107]

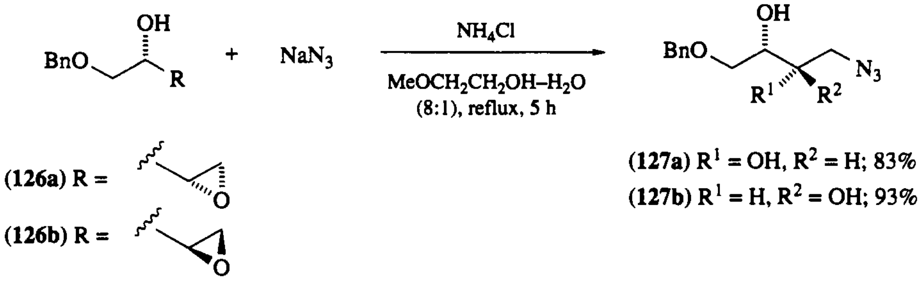


**Scheme 55**

In order to facilitate the reaction and to improve the regioselectivity of the oxirane ring opening, various procedures have been devised. Cation-exchange zeolites are efficient catalysts for the reaction of amines with epoxides.[108] The advantages of amine-doped alumina over the conventional homogeneous systems have been demonstrated.[109] Moderately acidic and basic zeolites show higher catalytic activity compared to strongly acidic or basic zeolites.[109,110]

Since enantiomerically pure 2,3-epoxy alcohols are readily available by the Sharpless epoxidation procedure,[105,111] the regioselective ring opening of 2,3-epoxy alcohols by nitrogen nucleophiles provides a convenient route to a variety of homochiral amines. A convenient procedure for the conversion of 2,3-epoxy alcohols to 1,2-epoxy-3-alkanols has been developed.[112]

1,2-Epoxy-3-alkanols (**126a**) and (**126b**) reacted with sodium azide to afford 1-azido-2,3-diols (**127a**) and (**127b**) in good yields (Scheme 56).[112]



(**126a**) R =

(**126b**) R =

(**127a**) R$^1$ = OH, R$^2$ = H; 83%

(**127b**) R$^1$ = H, R$^2$ = OH; 93%

**Scheme 56**

Under basic conditions, 2,3-epoxy alcohols rearrange to 1,2-epoxy-3-alkanols (the Payne rearrangement), resulting in an equilibrium mixture. Therefore, the oxirane ring opening of 2,3-epoxy alcohols with amines under Payne rearrangement conditions ($H_2O$, base) generally affords three possible isomers with rather poor regioselectivity.[112] Studies on the reaction of a series of 2,3-epoxy alcohols of general formula (**128**) and related compounds with sodium azide under nonisomerized conditions ($NH_4Cl$, in 2-methoxyethanol/$H_2O$) have revealed that the ratio of C-3 to C-2 attack is in the range 4:1–C-2 only.[113] In view of the results obtained, it has been demonstrated that, in addition to steric effects, electronic effects can play an important role in regioselectivity of oxirane ring opening reactions.[113] The reaction of epoxy alcohol (**129**) with benzylamine or sodium azide occurred exclusively at the position remote from the free hydroxy group, giving aminodiol (**130**) or azidodiol (**131**) as the sole product (Scheme 57).[114]

The rate and regioselectivity (C-3 attack) of the oxirane ring opening of 2,3-epoxy alcohols by nucleophiles are markedly increased by the addition of $Ti(OPr^i)_4$. Thus, the reaction of 2,3-epoxyhexanol with excess diethylamine in the presence of $Ti(OPr^i)_4$, 1,2-diol (**132**) and 1,3-diol (**133**) were formed in 90% yield in a ratio of 20:1, while, in the absence of the alkoxide, (**132**) and (**133**) were obtained in 4% yields in a ratio of 3.7:1 (Scheme 58).[115]

Regioselective C-2 amination of 2,3-epoxy alcohols can be realized by intramolecular oxirane ring opening of the carbamates prepared by the reaction of the epoxy alcohols with isocyanates.[116,117] In some cases, however, acyl transfer is a serious side reaction (Scheme 59).[117]

In this connection, intramolecular Michael addition of *O*-carbamates to α,β-unsaturated esters (Scheme 60),[118] iodo cyclization of allylic and homoallylic trichloroacetamidates[119] or aminomercuration of alkenic carbamates[119] has been used for the preparation of amino alcohols.

Tetraphenylstibonium triflate ($Ph_4SbOTf$; **134**) has been reported to be an effective catalyst for oxirane ring opening. Thus, otherwise unreactive cyclohexene oxide reacted smoothly with diethylamine in the presence of (**134**) ($CH_2Cl_2$, 40 °C, 20 h) to give (*E*)-2-diethylaminocyclohexanol in 75% yield.[120]

**Scheme 64**

As shown in Scheme 63, the regioselectivity of oxirane ring opening of 2,3-epoxy alcohols is increased in TMSN3–Lewis acid systems compared to conventional systems using sodium azide. It has been reported, however, that sodium azide supported on zeolite CaY facilitates the C-3 attack.[130]

A mild and highly stereoselective transformation of epoxides to azido alcohols by treatment with Et3Al–HN3 in toluene has been reported (Scheme 65).[131]

As described above, 1,2-azido alcohols can be stereospecifically prepared from epoxides. 1,2-Azido alcohols thus prepared reacted with triphenylphosphine or trialkyl phosphites to afford aziridines, where inversion of both centers of the original epoxides takes place (Scheme 66).[123,132] Intramolecular oxirane ring opening by nitrogen nucleophiles affords heterocyclic compounds.[133]

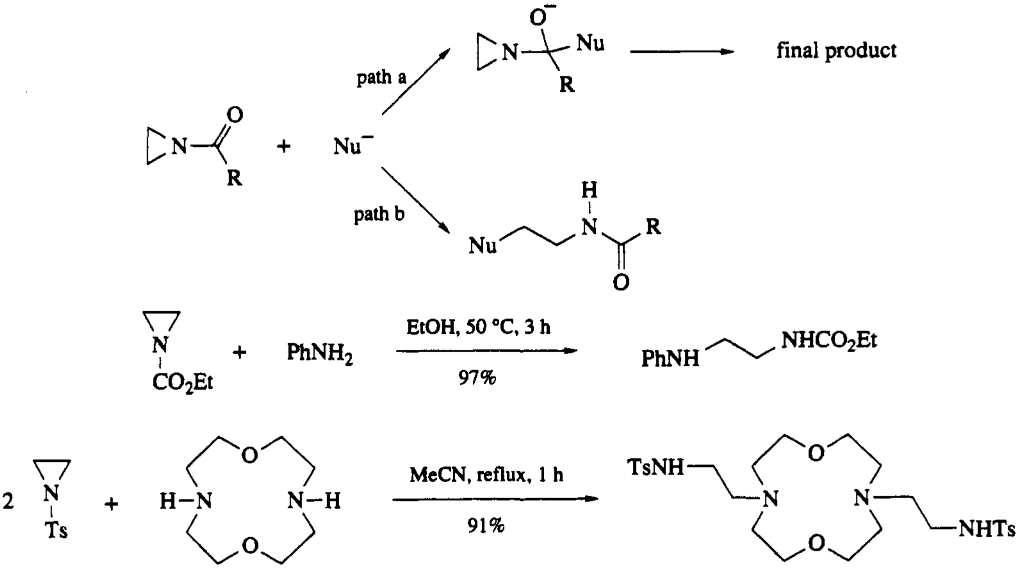
### 1.3.4.2 Aziridines

Aziridines can be prepared by various methods which involve dehydration of β-amino alcohols and dehydrohalogenation of β-amino halides.[134] Therefore, the reactions of aziridines with oxygen nucleophiles[135] and halide ions[136] will not be described in this section. A short review article has been published.[137]

Aziridines may be classified into two groups.[138] 'Activated aziridines (**143a**)' contain substituents capable of stabilizing a negative charge developed in the transition state of nucleophilic ring opening. The activated aziridines undergo ring-opening reactions with nucleophiles in the absence of catalysts (Scheme 67),[138,139] while 'unactivated aziridines (**143b**)' generally require acidic catalysts to promote the reaction. Since aziridine activated by a carbonyl group is an ambident electrophile, nucleophiles can attack the carbonyl carbon (Scheme 67, path a) and the ring carbon (Scheme 67, path b).

(**143a**) G = COR, $SO_2R$, $CO_2R$
(**143b**) G = H, alkyl, aryl



**Scheme 67**

Transformation of 1,3-diamino-2-propanol (**144**) into vicinal diamines has been reported.[140] Thus, the bis(benzyloxycarbonyl) derivative of (**144**) was mesylated to give (**145**), which was converted into 1-benzyloxycarbonylaziridine (**146**). Acetic acid and HCl reacted at the ring carbon of (**146**) affording 2,3-diamino-1-propanol (**147**) and 1-chloro-2,3-diaminopropane (**148**; Scheme 68). On the other hand, the reaction of (**146**) with Grignard reagents and sodio malonates resulted in the loss of the carbamate protecting group. In contrast, the sulfonamide derivative (**149**) could be converted into diamines (**151**) and (**152**) *via* 1-tosylaziridine (**150**; Scheme 68).

1-Ethoxycarbonylaziridine (**153**) has been reported to react with lithium amides affording carbonyl addition–elimination products (**154**; Scheme 69).[141] The reaction of (**153**) with trityllithium proceeded through path b in Scheme 67, while diphenylmethyllithium gave both 1-(diphenylacetyl)aziridine (path a; 33%) and *N*-(3-diphenylpropyl)carbamate (path b; 66%). Benzyllithium, *t*-butyllithium and lithium phenylacetylide afforded the corresponding symmetrical ketones (**155**).[141] 1-Acylaziridines (**156**) reacted with various organolithium and Grignard reagents to produce ketones (**157**) in high yields (Scheme 69).[142] 1-Tosylaziridine (**158**) reacted with 2-butynylmagnesiumm bromide to give ring-opened products (**159a** and **159b**; Scheme 69).[143]

The studies of the reaction of 1-substituted-2-phenylaziridines (**160a**), (**160b**) and (**160c**) with carbon nucleophiles have revealed that regioselectivity depends on the reagent used and reaction conditions. In general, methyl–metal reagents (MeMgBr, $Me_2CuLi$ and $MeCu{\cdot}BF_3$) tend to attack the C-2 of (**160**) to give (**161**; Scheme 70). 1-Tosylaziridine (**160b**) was found to be more reactive than (**160a**). MeLi caused decomposition of (**160b**) and displacement of the *N*-substituent of (**160a**). 1-Methylaziridine (**160c**) was decomposed by $Me_2CuLi$ or $MeCu{\cdot}BF_3$.[144]

In the reaction with carbon nucleophiles and with nitrogen nucleophiles, the reaction site on 1-substituted-2,2-dimethylaziridines (**163**) depends on the degree of leaving group activation. Thus, highly activated aziridine was attacked at C-3, while less activated aziridines were attacked at C-2 (Scheme 70).[145] The reaction of (**163**; G = Ts—, 2,5-$Cl_2C_6H_3SO_2$—, Bu$^t$C(O)—) with Grignard reagents (RMgX) is

more complicated; the product distribution depends on the activating group G, R, X and reaction conditions.[146]

Boron trifluoride etherate promotes the nucleophilic ring opening of unactivated aziridines with diorganocopperlithiums leading to both primary and secondary amines (Scheme 71).[147] Reaction of 1-benzyldiaziridine (**164a**) with $Me_2CuLi$ promoted by $BF_3 \cdot OEt_2$ afforded monobenzylamine (**165**) and piperidine derivative (**166**). When 1-benzyloxycarbonyl- or 1-tosyl-diaziridine (**164b**) and (**164c**) were allowed to react with $Me_2CuLi$ without Lewis acid catalysts, diamine (**167b**) or (**167c**) was obtained (Scheme 71).[132c]

**Scheme 71**

Sodium enolates of ketones and disodium enediolates of substituted phenylacetic acids reacted with activated aziridines to afford γ-amido ketones and γ-amidobutyric acids, respectively (Scheme 72).[148]

Aziridine-2-carboxylic acid esters can be utilized as versatile precursors for amino acid derivatives.[149] Although the product distribution resulting from the reaction of activated aziridine-2-carboxylates with amines depends on the structure of the reactants, the reactions with alcohols or thiols in the presence of acidic catalysts generally gave the α-amino acid derivatives (Scheme 73).[149,150] On the other hand, free 3-methyl-2-aziridinecarboxylic acids (**168**) reacted with thiophenol, cysteine and glutathione to afford β-amino acid derivatives with sulfur substituents at the α-position as the main product (Scheme 73).[151]

The reaction of activated aziridine-2-carboxylic acid methyl esters (**169**) with ethoxycarbonylmethylenetriphenylphosphorane resulted in the formation of phosphorane (**170**) along with phosphorane (**171**) and aziridine (**172**), with the exception of (**169d**), where (**172d**) was obtained as the sole product (Scheme 74).[152] Phosphorane (**170b**) was converted into 4-methylene-(2*S*)-glutamic acid (**173**).[152]

## 1.4.1 NITROSO COMPOUNDS

Some comprehensive reviews of the chemistry of *C*-nitroso compounds already exist.[1] Since the latest general review was published, no other relevant new findings on the formation of nitroso compounds by substitution processes have been reported. Reviews of special interest deal with the syntheses and properties of aliphatic fluoronitroso compounds,[2] nitrosoalkenes and nitrosoalkynes,[3] electrophilic *C*-nitroso compounds,[4] α-halonitroso compounds[5] and nitrosation mechanisms.[6]

Indirect replacement of the α-hydrogen atom of carboxylic esters by the nitroso group is remarkable.[7] This procedure uses ketene *O*-alkyl *O'*-silyl acetals (**1**), generated from carboxylic esters, which are treated with nitric oxide or isopentyl nitrite in the presence of titanium(IV) chloride. In the absence of an α-hydrogen α-nitroso esters (**2**) are obtained. α-Nitroso esters with an α-hydrogen undergo isomerization to oximes of α-keto esters (**3**; equation 1). Similarly, silyl enol ethers of aldehydes or ketones can be used instead of the carbonyl compound itself for nitrosation. Thus, treatment of enol ether (**4**) with nitrosyl chloride gives the α-nitroso aldehyde (**5**; equation 2),[8] which is quite stable at 0 °C, but dimerizes at room temperature.

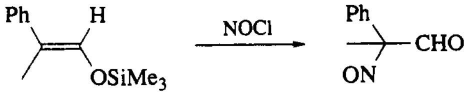
(**1**) $R^1$ = Me, Et, Ph; $R^2$ = Me, Ph (**2**) (**3**)



(2)

(**4**) (**5**)

## 1.4.2 NITRO COMPOUNDS

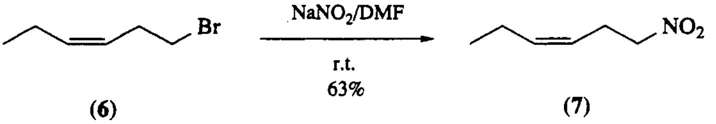
There are several general reviews of this area of chemistry.[9] This section covers mainly novel methods and improvements to established procedures for the preparation of nitro compounds which have been published within the last 10 years.

### 1.4.2.1 Aliphatic Nitro Compounds

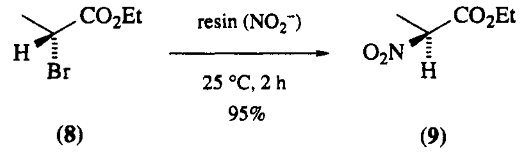
### *1.4.2.1.1 Nitroalkanes*

Substitution of halogen by a nitro group is still one of the most important methods for the laboratory preparation of primary and secondary nitroalkanes. With sodium nitrite, solvents such as dimethylformamide and dimethyl sulfoxide are employed. For example, (*Z*)-1-nitrohex-3-ene (**7**) was prepared from (*Z*)-1-bromohex-3-ene (**6**; equation 3).[10] For the transformation of α-bromo esters into α-nitrocarboxylic esters the use of an anion-exchange resin in anhydrous benzene or ethanol has been recommended. With

(*R*)-ethyl 2-bromopropanoate (**8**) under these conditions the corresponding (*S*)-nitro ester (**9**) is formed with inversion of configuration (equation 4), but it racemizes during the reaction.[11] A short review of the preparation of chiral nitro compounds exists.[12]

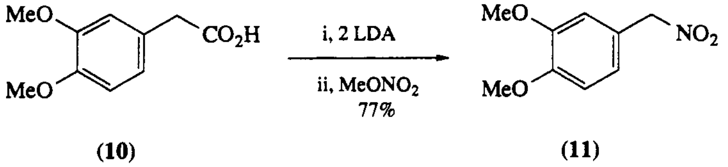


(3)



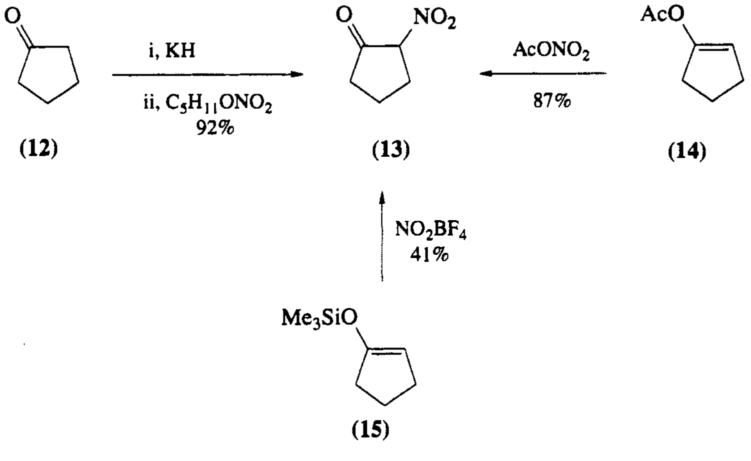
(4)

The condensation of dianions of ring-methoxylated phenylacetic acids like (**10**) with methyl nitrate provides a general, one-step procedure to the corresponding phenylnitromethane (**11**; equation 5).[13] Methods for the preparation of nitroacetic esters have been summarized.[14]



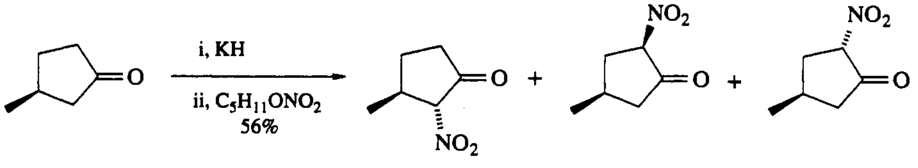
(5)

The alkyl nitrate nitration, a reaction of a nitrate ester in the presence of a base with active methylene compounds, enables the introduction of a nitro group at carbons in the α-position to the activating group. This reaction has been applied to a variety of active methylene compounds such as ketones, aliphatic carboxylic esters, amides, lactams, alkane sulfonate esters, activated toluenes and heterocyclic compounds.[15] The preparation of cyclic α-nitro ketones as well as the synthetic utility of these synthetic intermediates has been reviewed.[16] 2-Nitrocyclopentanone has been synthesized by three routes starting with cyclopentanone (**12**; Scheme 1).[17] Treatment of the potassium enolate of cyclopentanone with pentyl nitrate gives 2-nitrocyclopentanone (**13**) in 92% yield. An alternative route to 2-nitrocyclopentanone (**13**) in 87% yield is the nitration of 1-acetoxycyclopentene (**14**) with acetyl nitrate, generated *in situ* from nitric acid and acetic anhydride. Nitration of 1-trimethylsiloxycyclopentene (**15**) with nitronium tetrafluoroborate gives (**13**) in a yield of 41%. Enol ethers (**14**) and (**15**) can be obtained from cyclopentanone.



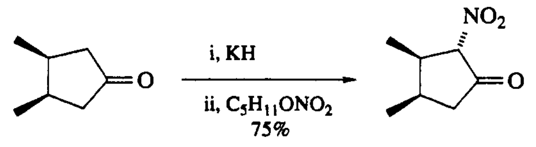
**Scheme 1**

Generating the enolates of substituted cyclic ketones by using potassium hydride leads to the thermodynamic mixture of enolates, and therefore nitration of potassium enolates often does not allow for a regiospecific synthesis of α-nitro ketones. For example, the potassium enolate of 3-methylcyclopentanone (**16**) gives three isomers in a ratio (**17**):(**18**):(**19**) = 2:1:1 (equation 6). On treatment of the potassium enolate of *cis*-3,4-dimethylcyclopentanone (**20**) with pentyl nitrate *trans*-2-nitro-*cis*-3,4-dimethylcyclopentanone (**21**) is formed diastereoselectively (equation 7).[18]



(6)

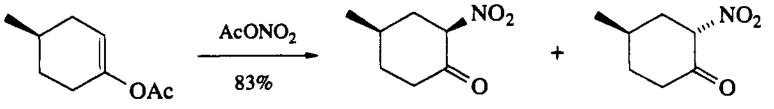
(**16**) (**17**) 50% (**18**) 25% (**19**) 25%



(7)

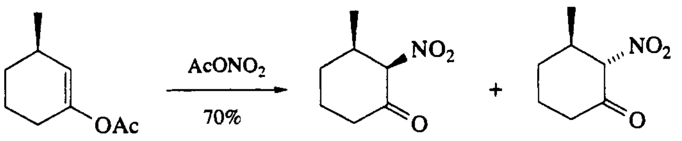
(**20**) (**21**)

The nitration of enol acetates with acetyl nitrate is a regiospecific electrophilic addition to the β-carbon of the enol acetate, followed by a hydrolytic conversion of the intermediate to the α-nitro ketone. With enol acetates of substituted cyclohexanones the stereochemistry is kinetically established. So, 1-acetoxy-4-methylcyclohexene (**22**) yields the thermodynamically less stable *trans*-4-methyl-2-nitrocylohexanone (**24**) in greater proportion (*cis*:*trans* = 40:60) (equation 8). This mixture can be equilibrated in favor of the thermodynamically more stable *cis* diastereomer (**23**) (*cis*:*trans* = 85:15). Nitration of 1-acetoxy-3-methylcyclohexene (**25**) leads to *trans*-3-methyl-2-nitrocyclohexanone (**26**), which is also the thermodynamically more stable isomer (equation 9).[19] No stereoselection occurs in the kinetically controlled nitration with acetyl nitrate of 1-acetoxy-5-methylcyclohexene (**27**; equation 10), but the 1:1 mixture of the 5-methyl-2-nitrocyclohexanones can be equilibrated in favor of the *trans* diastereomer (**28**) (*cis*:*trans* = 10:90). 2-Alkyl-2-nitrocyclohexanones cannot be prepared in acceptable yields by nitration of the corresponding enol acetates with acetyl nitrate.



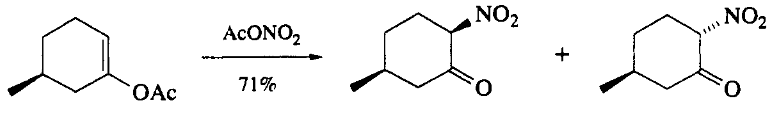
(8)

(**22**) (**23**) 40% (**24**) 60%



(9)

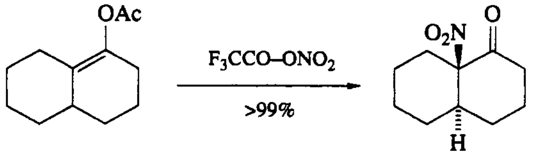
(**25**) <1% (**26**) >99%



(10)

(**27**) 50% (**28**) 50%

It has been demonstrated that a mixture of ammonium nitrate and trifluoroacetic anhydride is a very effective system for the nitration of enol acetates. It is assumed that trifluoroacetyl nitrate is produced, which is a much more powerful nitrating agent than acetyl nitrate. So, 2-methyl-2-nitrocyclohexanone can be obtained from 2-methyl-1-acetoxycyclohexene in nearly quantitative yield. Also, the enol acetate of decalone (**29**) was quantitatively converted to *trans*-10-nitro-1-decalone (**30**; equation 11).[20]



**(29)** **(30)**

(11)

Nitration of 2-methyl-1-(trimethylsiloxy)cyclohexene (**31**) with nitronium tetrafluoroborate leads to 2-methyl-2-nitrocyclohexanone (**32**; equation 12), while 6-methyl-1-(trimethylsiloxy)cyclohexene (**33**) gives under similar conditions a 30:70 mixture of *cis*- and *trans*-6-methyl-2-nitrocyclohexanone (equation 13).[21] The desilylative nitration of allylsilanes with nitronium tetrafluoroborate proceeds readily. The reaction is considered to pass through initial electrophilic attack of the nitronium ion on the allyl system followed by desilylative elimination. So, on treatment of 1-(trimethylsilyl)but-2-ene (**34**) with nitronium tetrafluoroborate the product is 3-nitrobut-1-ene (**35**) and not 1-nitrobut-2-ene (equation 14).[22]

The synthesis of polynitropolycyclic cage molecules has been reviewed.[23]

### *1.4.2.1.2 Conjugated nitroalkenes*

There are reviews dealing with conjugated nitroalkenes in organic synthesis,[24] nitroenamines,[25] the oxyalkylation of carbonyl compounds with conjugated nitroalkenes[26] and the use of conjugated nitroalkenes in the synthesis of heterocyclic compounds.[27] In this section mainly the preparation of nitroalkenes starting from alkenes is described.

In principle nitroalkenes should be available from direct nitration of vinyl carbanions. However, this reaction is not practical due to the potential anionic polymerization. But vinylstannanes obtained from ketones can be used instead of vinyl carbanions. Tetranitromethane is effective in replacing tin by nitro at unsaturated carbon. This method has been used to prepare several alkyl-substituted 1-nitrocyclohexenes and 1-nitrocycloheptenes (Scheme 2).[28]

Dinitrogen tetroxide addition to alkenes in the presence of oxygen leads to mixtures of *vic*-dinitro compounds, β-nitro nitrites and nitrates. Nitroalkenes may be prepared without isolation of the adducts by treating the mixture with basic reagents. 1-Nitrocyclooctene (**37**) can be obtained from cyclooctene (**36**) by this route (equation 15).[29] The same reaction sequence has been used for the regioselective and stereoselective preparation of (*E*)-2-nitroethenyltrimethylsilane (**38**; equation 16).[30] In the presence of iodine with alkenes and dinitrogen tetroxide β-nitroalkyl iodides are formed. These give 1-nitroalkenes

Nitryl iodide, generated *in situ* by reaction of silver nitrite with iodine, has been used for chemoselective nitration of substituted styrenes (equation 18).[33] Reaction of alkenes with sodium nitrite and iodine in the presence of ethylene glycol provides 1-nitroalkenes without using a base.[34] Nitrovinylsilanes have been prepared by addition of nitryl chloride to a vinylsilane followed by elimination of hydrogen chloride with base from the resulting chloronitrosilane (equation 19).[30,35] In a similar reaction sequence glycals could be transformed to 2-nitroglycals by treatment with nitronium tetrafluoroborate followed by elimination of hydrogen fluoride.[36]

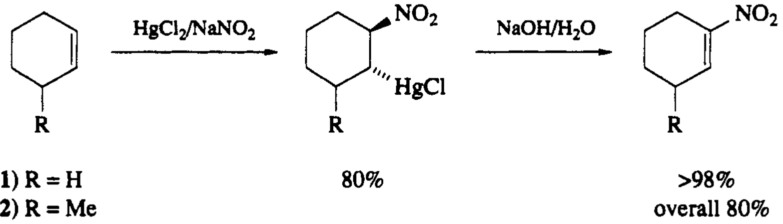
Addition of mercury(II) nitrite, generated *in situ* from mercury(II) chloride and sodium nitrite, provides a general route to 1-nitroalkenes. Thus, on treatment with sodium hydroxide or a tertiary amine the adducts are converted into nitroalkenes in good yields. The clean formation of 2-nitronorbornene from norbornene indicates that carbonium ion rearrangement is not a problem. A further point of interest is the regioselectivity of nitromercuration, illustrated by the nitration of (**42**; Scheme 3).[37] The nitromercuration method has been used for the preparation of 3-nitrocycloalkenones[38] and (*E*)-2-nitroethenyltrimethylsilane.[7]



Scheme 3

Another route to conjugated nitroalkenes is based on nitroselenenylation of alkenes. Although the overall yield of nitroalkenes is slightly lower than for nitromercuration, the advantage of nitroselenenylation over nitromercuration is avoidance of aqueous media. Treatment of alkenes with benzene selenyl bromide followed by addition of silver nitrite provides a mixture of 2-nitroalkyl and 2-hydroxyalkyl phenyl selenides. The latter products can be suppressed by addition of mercury(II) chloride. The adducts are converted into conjugated nitroalkenes on oxidation with hydrogen peroxide.[39,40] By using (*E*)- and (*Z*)-oct-4-ene it has been established that the reaction is stereospecific (Scheme 4). Unsymmetrical alkenes give regioisomeric mixtures. Thus on addition, 1-hexene yields Markovnikov product and anti-Markovnikov product in the ratio 78:22.[40] In a similar reaction sequence trialkyl (2-nitro-1-alkenyl) silanes (nitrovinylsilanes) can be prepared starting from vinylsilanes (Scheme 5). In this case the regiochemistry of addition is controlled by the β-effect of the silyl group. This reaction is also stereoselective.[41]

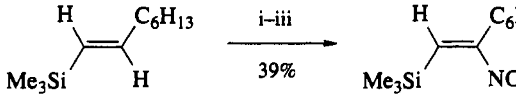
Scheme 4



i, PhSeCl; ii, AgNO$_2$/HgCl$_2$; iii, H$_2$O$_2$

Scheme 5

A procedure for the efficient synthesis of 1-nitro-1,3-dienes in two steps involves the *in situ* preparation of trifluoroacetyl nitrate from ammonium nitrate and trifluoroacetic anhydride, and addition to 1,3-dienes to give mixtures of adducts. A mixture of the adducts on treatment with base eliminates to afford 1-nitro-1,3-diene. In the case of isoprene the reaction leads chemo-, regio- and stereo-selectively to (*E*)-2-methyl-1-nitrobuta-1,3-diene (**43**; Scheme 6). In contrast nitrotrifluoroacetoxylation of (*E*)-penta-1,3-diene followed by elimination gives an inseparable mixture of (*E*,*E*)-1-nitropenta-1,3-diene and (*E*)-4-nitropenta-1,3-diene (Scheme 6).[42] Similarly, ethyl vinyl ether has been transformed with acetyl nitrate to ethyl (*E*)-2-nitrovinyl ether.[43]

1-Nitro-2-(trialkylsilyl)alkynes can be synthesized by nitration of bis(trialkylsilyl)alkynes with nitronium tetrafluoroborate or nitronium hexafluorophosphate (equation 20), with nitryl fluoride addition across the triple bond as the major reaction.[44]

### 1.4.2.2 Aromatic Nitro Compounds

This field has been reviewed recently in a monograph.[45] For syntheses of vicinally substituted nitropyridines an extensive review is accessible.[46] In a recent monograph the preparation of nitroazoles has been discussed.[47] Introduction of a nitro group in an aromatic ring is usually carried out *via* electrophilic aromatic substitution using nitric acid, its metal salts, mixed anhydrides, nitrate esters or nitronium salts.[48–50] Most often these methods require subsequent aqueous work-up. In the case of alkylbenzenes this can be avoided by using a perfluorinated resinsulfonic acid (Nafion-H). So, a number of alkylbenzenes have been nitrated with *n*-butyl nitrate, acetone cyanohydrin nitrate or dinitrogen tetroxide over Nafion-H catalyst.[51]

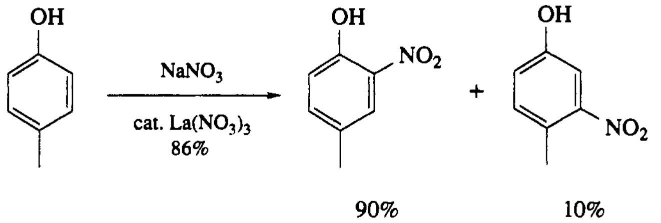
Trifluoroacetic nitrate, prepared *in situ* from ammonium nitrate and trifluoroacetic anhydride, has been used for nitration of aromatic compounds at room temperature with high yields. While benzoic acid gives *m*-nitrobenzoic acid nearly quantitatively, nitrobenzene is not reactive under these conditions. Attack at the *ortho* position rather than the *para* position is observed with activated benzene derivatives like anisole. However, this system oxidizes phenols to quinoid products.[52]

The effect of crown ethers on the selectivity of nitration of aromatic hydrocarbons and anisole has been studied with a mixture of trifluoroacetic anhydride and tetrabutylammonium nitrate as nitration agent. The largest effects on selectivity have been observed with 21-crown-7, which causes *ortho–para*-directing groups to act essentially as *para*-directing groups.[53]

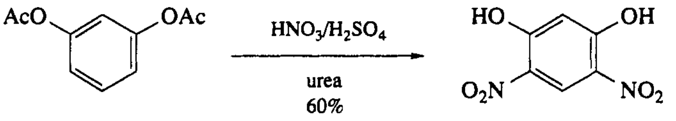
Phenols can be mononitrated in a two-phase system (ether/water) by sodium nitrate and aqueous hydrochloric acid in the presence of a catalytic amount of lanthanum(III) nitrate in yields generally above 80%. Phenol itself gives 2:1 *ortho:para* nitration, while phenols substituted in the *para* position give predominantly *ortho* nitration with some *meta* nitration (equation 21). As shown recently nitration of phenols in the two-phase system occurs even without lanthanum(III) nitrate. By use of sodium nitrate, aqueous sulfuric acid and a catalytic amount of sodium nitrite in the two-phase system mononitration of phenols can be achieved in high yields. Under these conditions starting from 3-substituted phenols in addition to the nitro compounds formation of quinones has been observed.[54,55] Polyhydroxy aromatics are typically difficult to nitrate directly. Thus, 4,6-dinitroresorcinol (**45**) has been synthesized from resorcinol diacetate (**44**) with nitric acid or mixed solutions of nitric acid/sulfuric acid containing urea as a nitrous trap (equation 22).[56]

A useful reagent for the regioselective nitration of aromatic amines is urea nitrate in sulfuric acid. *p*-Nitroanilines are formed exclusively. When the *para* position is blocked, nitration occurs to give the *m*-nitroaniline derivative.[57]

Silica gel supported cerium(IV) ammonium nitrate (CAN) has been employed for controlled nitration of some naphthalene derivatives. While treatment of hydroxynaphthalenes and polynuclear arenes with cerium(IV) ammonium nitrate absorbed on silica gel without a solvent affords mononitro derivatives, the reaction of the same substrates with cerium(IV) ammonium nitrate in solution affords a considerable per-



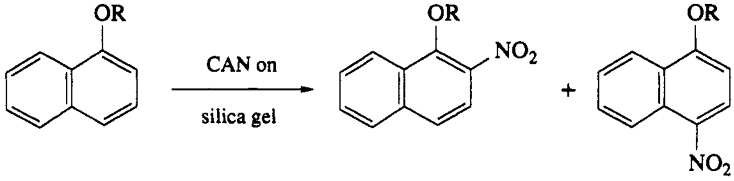
(21)



(44) (45)

(22)

centage of dinitro derivatives or quinones. Thus, 1-hydroxynaphthalene (**46**) is converted into a mixture of 4,6-dinitro- and 2,4-dinitro-2-hydroxynaphthalene, when treated with cerium(IV) ammonium nitrate in acetic acid, whereas the 2-nitro- and 4-nitro-naphthalene derivatives (**47**) and (**48**) are obtained when the same nitrating agent on silica gel is used. Under similar conditions 1-methoxynaphthalene (**49**) gives 1-methoxy-4-nitronaphthalene (**50**) exclusively (Scheme 7).[58]



(**46**) R = H 80% (**47**) 53% (**48**) 47%
(**49**) R = Me 65% 0% (**50**) 65%

**Scheme 7**

Novel reagents consisting of metallic nitrates impregnated on montmorillonite have been introduced in aromatic nitration.[59] With clay-supported copper(II) nitrate in the presence of acetic anhydride it is possible to nitrate toluene quantitatively with a high *para* preference (79% *para*, 20% *ortho*, 1% *meta*).[60] Also, good *para* selectivities have been found on nitration of some other aromatic hydrocarbons with copper(II) nitrate on clay.[61] Halobenzenes are mononitrated with clay-supported copper(II) nitrate in the presence of acetic anhydride. Compared to other methods high *para:ortho* ratios are obtained under these conditions.[62]

When nitration of phenols is performed with clay-supported iron(III) nitrate at room temperature, exclusively *o*- and *p*-nitrophenols are formed. No *meta* nitration occurs. With *meta*-substituted phenols, one of the *ortho* positions is favored with respect to the other (Scheme 8).[63]

## 1.4.3 HYDROXYLAMINES

Methods for preparation of hydroxylamine derivatives have been reviewed in detail recently.[64] Here, mainly new developments concerning the synthesis of hydroxylamines by substitution processes with heterobond formation are presented. Reduction of nitro, nitroso, oxime and nitrone derivatives as well as direct oxidation of amines leading to hydroxylamine compounds will not be considered.

### 1.4.3.1 Carbon–Heteroatom Linkage with Nucleophilic Heteroatoms

Direct monoalkylation of hydroxylamine is usually not a good preparative method because of the problems with further alkylation on nitrogen. However, in a one-pot procedure hydroxylamine hydro-

Although several methods have been reported, the synthesis of *N*-monoalkylhydroxylamines from alkyl halides or sulfonates has remained difficult. Relating to this a new preparation of *N*-alkylhydroxylamines is based upon *N*-alkylation of isoxazole derivative (**52**). Besides 2-propyl iodide several primary alkyl halides have been described as the alkylation agent in this procedure (equation 23).[66]

On application of protecting groups it has to be considered that on deprotection with hydrogen, cleavage of the N—O bond can occur. Thus, the ε-hydroxynorleucine derivative (**53**) was subjected to Mitsunobu reaction with a protected hydroxylamine to yield the *N*-alkylated compound (**54**), but hydrogenolysis gave only lysine (**55**) instead of *N*-hydroxylysine (Scheme 10).[67] Alkylation of the carbamate (**57**), available from di-*t*-butyl dicarbonate (**56**) and *O*-benzylhydroxylamine, with a primary or secondary mesylate or iodide gives carbamates (**58**) in good yields. Similarly, *N*-benzyloxyureas (**61**) have been alkylated exclusively on the benzyloxy-substituted nitrogen to form (**62**). Acidolysis of (**58**) leads to alkylbenzyloxyamines (**59**). Deprotection of (**58**) and (**62**) can be achieved by catalytic transfer hydrogenolysis using ammonium formate and palladium on charcoal (Scheme 11).[68]

The palladium(0)-catalyzed reaction of allyl esters with hydroxylamine and substituted hydoxylamines is a valuable route to *N*-allylhydroxylamines (equations 24 and 25). The absolute configuration of the products (equation 25) has not been proved. In other examples the regioselectivity of the reaction has been demonstrated.[69]

A number of syntheses of *N*-hydroxy-α-amino acids and derivatives thereof have been reported.[70] α-Bromocarboxylic acids or their *t*-butyl esters can be treated with hydroxylamine or *O*-alkylated hydroxylamines to give the corresponding hydroxylamine derivatives. *N*-Benzyloxy-L-alanine has been obtained by reaction of (*R*)-α-bromopropionic acid with *O*-benzylhydroxylamine. But due to bromide exchange the optical yield was low.[71] Anchimeric assistance of a suitable attached thio group can bring

**Scheme 12**

Hydroxylamines usually react with acid chlorides to give mixtures of *N*-, *O*- and poly-acylated products. In contrast reaction of tris(trimethylsilyl)hydroxylamine (**65**) with aliphatic acid chlorides leads selectively under *N*-monoacylation to the corresponding hydroxamic acids (**66**; equation 26).[76] While diphenylphosphinic chloride (**68**) is attacked by the oxygen of hydroxylamine to yield *O*-(diphenylphosphinyl)hydroxylamine (**67**; Scheme 13), *N*-(diphenylphosphinyl)hydroxylamine (**69**) can be obtained by treatment of diphenylphosphinic chloride with *O*-trimethylsilylhydroxylamine followed by removal of the silyl blocking group (Scheme 13).[77] *O*-Acylation of arylhydroxylamines can be achieved with acyl cyanides.[78]

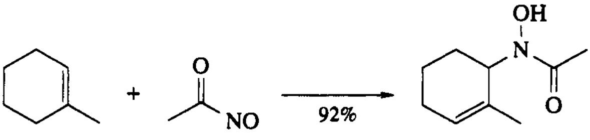
**Scheme 14**

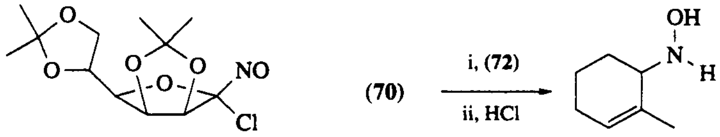
### 1.4.3.2 Carbon–Nitrogen Linkage *via* Electrophilic Amination

Both inter- and intra-molecular ene reactions of acylnitroso compounds with alkenes provide *N*-alkylhydroxylamine derivatives. The regiochemistry observed is in agreement with C—N bond formation by electrophilic nitrogen ahead of abstraction of allylic hydrogen by nitroso oxygen. Thus, reaction of 1-methylcyclohexene (**70**) with *in situ* generated nitrosocarbonylmethane yields a single product (**71**; equation 27).[80] The chiral α-chloronitroso derivative (**72**) reacts with several alkenes regio- and diastereo-selectively to give nitrone hydrochlorides, which can be hydrolyzed to optically active allylic hydroxylamines (equation 28). The % *ee* values have not so far been determined.[81]



(27)

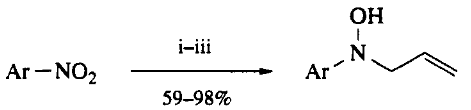
(**70**) (**71**)



(28)

(**72**)

Bis(silyl)ketene acetals undergo silatropic ene reaction with nitrosobenzene to give *N*-hydroxyamino acid derivatives.[82] When allylmagnesium chloride is reacted with nitroarenes, unstable adducts result. Reduction of these adducts with LAH in the presence of palladium on charcoal leads to *N*-allyl-*N*-arylhydroxylamines (**73**; Scheme 15). With alkyl Grignard reagents this reaction is negligible.[83]



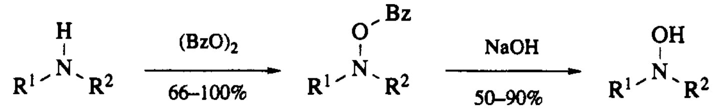
(**73**)

i, allylMgCl; ii, LAH; iii, NH$_4$Cl

**Scheme 15**

### 1.4.3.3 Nitrogen–Oxygen Linkage

A two-step procedure for the oxidation of amines to hydroxylamines involves nucleophilic displacement along the peroxide bond of dibenzoyl peroxide and saponification of the intermediate *O*-benzoylhydroxylamine. Primary and secondary amines have been oxidized in this way (equation 29).[84] Related reactions for transformation of amines to *O*-(arylsulfonyl)- and *O*-phosphinyl-hydroxylamines have been described by means of bis(arylsulfonyl)[85] and bis(diphenylphosphinyl) peroxide, respectively.[86,87]



(29)

A method for the synthesis of optically active hydroxylamines from optically active primary amines with retention of configuration is based on the conversion of the amines to corresponding benzylimines followed by oxidation to 3-phenyloxaziridines (**74**). Subsequent hydrolysis leads to hydroxylamines (Scheme 16).[88] This sequence has been extended to the synthesis of optically active *N*-hydroxy-α-amino acid esters.[89]

## 1.4.4 HYDRAZINO COMPOUNDS

A detailed review of the literature to 1967 is available, as well as several more recent reviews.[90]

### 1.4.4.1 Carbon–Nitrogen Linkage with Nucleophilic Nitrogen

Direct alkylation of hydrazine itself with halides and sulfates usually gives mixtures of mono- and poly-alkylated hydrazines. It is possible to get useful yields of the monoalkylhydrazine by using an excess of hydrazine. Several specific procedures leading to monoalkylhydrazines are based on selective alkylation of hydrazine derivatives with protecting groups attached. So, easily prepared acetone *N*-(diethoxyphosphoryl)hydrazone (**75**) can be used. Phase-transfer catalyzed *N*-alkylation of (**75**), followed by deprotection with *p*-toluenesulfonic acid provides monoalkylhydrazine sulfonates (**76**; Scheme 17).[91] Similarly, *N*-alkyl-*N*-arylhydrazines have been prepared by phase-transfer catalyzed *N*-alkylation of arylhydrazones (Scheme 18).[92] An efficient, one-pot method for the synthesis of a variety of polysilylated hydrazines employs hexamethyldisilane (equation 30).[93] Polysilylated hydrazines were found to react with aldehydes or ketones to give hydrazones under anhydrous conditions. By treatment with triphenylphosphine and diethyl azodicarboxylate primary and secondary alcohols can be converted to hydrazine derivatives (equation 31).[94]

Bidentate alkylating agents may react with hydrazines at both nitrogens to close a ring, if the ring size is suitable. If hydrazine itself is used, further alkylation under formation of a second ring to tetrasubstituted hydrazine derivatives sometimes occurs. In these cases a better procedure is to take an azodicarboxylate derivative and remove the protecting group after alkylation.[95]

Alkylation of hydrazine with α,β-unsaturated carbonyl derivatives or carbonyl derivatives with a leaving group in the β-position provides pyrazole derivatives. For example, treatment of the tosylate (**77**), obtained from L-serine, with anhydrous hydrazine gives racemic pyrazolidinone (**78**). It appears that pyrazolidinone (**78**) or one of the intermediates suffers base-catalyzed racemization (equation 32).[96] Starting from β-lactam (**79**) seven-membered cyclic hydrazine (**80**) has been formed by ring closure in an unusually high (84%) yield (equation 33).[97] Reaction of (π-allyl)palladium complex (**81**) with dimethylhydrazine produces exocyclic diene (**82**) in a modest (29%) yield, but this is still more efficient than the reaction of 2,3-bis(chloromethyl)butadiene (**83**) with dimethylhydrazine (equation 34).[98]

### 1.4.4.2 Carbon–Nitrogen Linkage *via* Electrophilic Amination

Azodicarboxylate esters are the reagents of choice for electrophilic *N*-amino amination leading to hydrazine derivatives. Besides Grignard reagents[99] and alkyl or aryl lithium compounds,[100] enolates[101] and silyl enol ethers[102] derived from ketones have been aminated by this method. In particular, di-*t*-butyl azodicarboxylate has been reacted with a variety of chiral enolates (Scheme 19)[103,104] and chiral silyl ketene acetals (Schemes 20 and 21)[105,106] to afford α-hydrazino acid derivatives with high diastereoselectivities in good chemical yields. By the same method α-hydrazino-β-hydroxy esters (**84**) with % *ee* values up to 75% have been obtained from α-hydroxy esters (Scheme 22).[107] An even higher stereoselection results by using dioxanone (**85**) instead of the acyclic β-hydroxy ester (Scheme 23).[108]

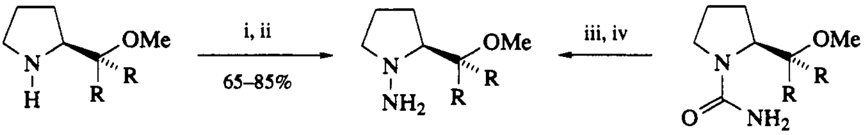
### 1.4.4.3 Nitrogen–Nitrogen Linkage

A widely used method for preparing *N*,*N*-disubstituted hydrazines is the reduction of *N*-nitrosoamines obtained by nitrosation of secondary amines. There are several methods for effecting this reduction based on dissolving metals, low-valent titanium reagents,[109] hydride reagents and catalytic reduction with hydrogen. For example, several chiral auxiliaries derived from (*S*)-proline have been synthesized by reduction of the corresponding *N*-nitrosoamine (Scheme 24).[110] But *N*-nitrosoamines are carcinogenic intermediates. Therefore, an alternative route to (*S*)- and (*R*)-1-amino-2-methoxymethylpyrrolidine ('SAMP' and 'RAMP') (**86**; R = H) has been described. This procedure involves treatment of the urea (**87**) or its enantiomer, obtained from (*S*)- or (*R*)-proline, with potassium hypochlorite followed by elimination of hydrogen chloride with potassium hydroxide (Scheme 24). Yields based on proline range from 50 to 58%.[111]

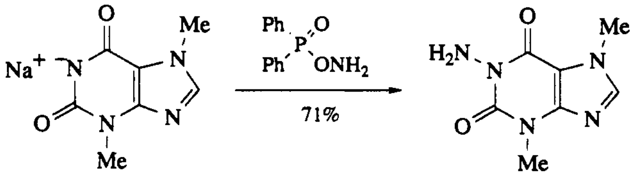


**(86)** **(87)**

i, Bu$^t$ONO; ii, LAH; iii, KOCl; iv, KOH

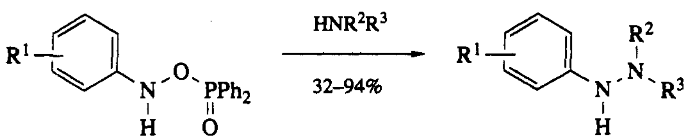
Scheme 24

Electrophilic *N*-aminations have been performed with hydroxylamine-*O*-sulfonic acid (HOSA),[112] *O*-(2,4-dinitrophenyl)hydroxylamine and *O*-mesitylenesulfonylhydroxylamine. The use of HOSA is mainly restricted to aqueous reaction media. Imide sodium salts of some heterocycles such as theobromine (**88**) can be converted to hydrazine derivatives by treatment with *O*-(diphenylphosphinyl)hydroxylamine (equation 35).[113] This reaction has been extended to synthesis of *N*-arylhydrazines, where R$^2$ and R$^3$ are hydrogen, alkyl or aryl (equation 36).[114] Similarly, trisubstituted hydrazines can be prepared by the use of *N*-aryl-*O*-acetylhydroxylamines and secondary amines.[115] A recent publication[116] concerning the synthesis of 1-acyl-2-alkylhydrazines from hydroxamic acids and amines in the presence of activating agents has been found to be erroneous; no N—N bond formation occurs under these conditions.[117]



**(88)**

(35)



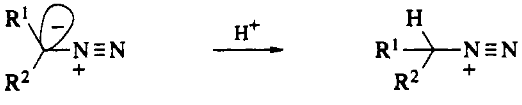
(36)

## 1.4.5 PREPARATION OF DIAZOALKANES

### 1.4.5.1 Properties of Diazoalkanes

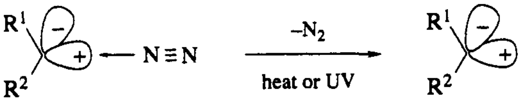
The synthesis and properties of diazo compounds have been covered in an excellent review by Regitz and Maas.[118] This section does not attempt to duplicate that review. Rather, two key areas are covered: the most practical methods for the preparation of diazo-containing compounds, and use of these intermediates in organic synthesis. To understand these areas, however, it is important first to appreciate the structure, bonding and reactivity of the diazo functional group.

One model for bonding in a diazo compound would be the ylide (**89**; equation 37).[119] Unlike many other ylides, diazoalkanes are stable to air and water. With acid, however, protonation can lead to the highly reactive salt (**90**), the functional equivalent of the corresponding carbocation. As the substituents on the diazo group are made increasingly electron withdrawing, the ylide becomes less basic, and thus more stable to acid. Reaction of a diazo compound with a transition metal can also often be understood as proceeding *via* initial donation of electron density by (**89**) to a coordinatively unsaturated metal center.



(**89**) (**90**) (37)

The diazo compound can alternatively be viewed as a coordination complex (**91**) between a carbene and $N_2$ (equation 38).[119] The coordination is weak, so any input of energy, either *via* heating or UV radiation, can lead to $N_2$ loss, liberation of the free carbene and subsequent reaction.

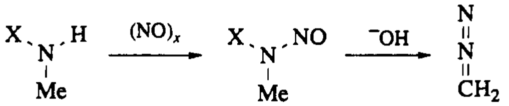


(**91**) (**92**) (38)

It should be remembered that many diazo compounds, especially those having electron-withdrawing groups, are quite stable. Ethyl diazoacetate, for instance, can be stored for years. As methods for the preparation of diazo compounds improve, they will become increasingly important in organic synthesis.

### 1.4.5.2 Diazomethane

The best known and most widely used diazoalkane is diazomethane (**95**; equation 39). Preparative methods for diazomethane involve, in general, the nitrosation of a methylamine derivative (**93**), followed by cleavage under alkaline conditions. Methylamine derivatives used have included the urethanes,[120] ureas,[121] carboxamides,[122] sulfonamides,[123] guanidines[124] and even the methylamine adducts of unsaturated ketones[125] and sulfones.[126] *N*-nitroso-*N*-methyl *p*-toluenesulfonamide (Diazald, Aldrich) is currently the most commonly used diazomethane precursor. Diazomethane is both toxic and explosive. Although in the past it has been purified by codistillation with ether, it is now usually generated, stored and used as an ether solution without distillation.

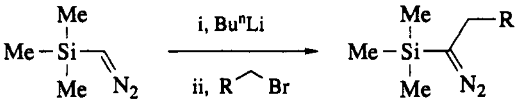


(39)

**(93)** **(94)** **(95)**

### 1.4.5.3 Trimethylsilyldiazomethane

Trimethylsilyldiazomethane (**96**), prepared in excellent yield from chloromethyltrimethylsilane,[127] is now commercially available (Petrarch). Trimethylsilyldiazomethane is readily lithiated and alkylated (equation 40).[128] Synthetic applications of the resultant silyldiazoalkanes (**97**) have not yet been extensively explored. These might, for instance, react smoothly with acid chlorides to give diazoketones (see Section 1.4.6.1).

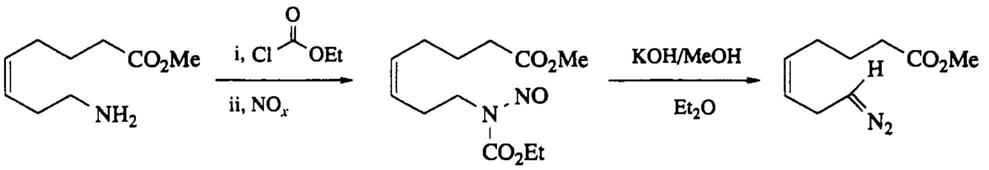


(40)

**(96)** **(97)**

### 1.4.5.4 Higher Diazoalkanes

The synthetic methods outlined above for diazomethane work well, in general, for the higher diazoalkanes. Again, these are usually generated and handled as solutions in diethyl ether. In the special case of the conversion of the amine (**98**) to diazoalkane (**100**), the urethane approach proved most effective (equation 41).[129]



(41)

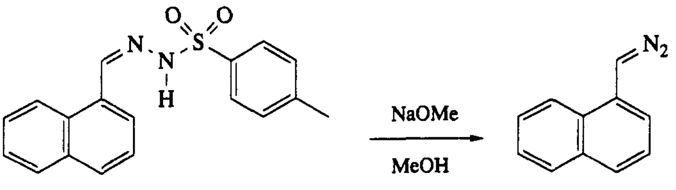
**(98)** **(99)** **(100)**

The *N*-nitrosation reaction works well for a variety of amine derivatives.[130] The substance to be nitrosated is dissolved in an inert solvent ($CCl_4$ has classically been used, but diethyl ether works just as well) in which anhydrous potassium acetate has been suspended. The brown vapor generated by addition of concentrated sulfuric acid to sodium nitrite (in a separate flask) is then blown through with a gentle stream of nitrogen. Formation of the *N*-nitroso derivative (**99**) is conveniently monitored by TLC. It is usually complete in 1–2 h.

The hydrolysis of (**99**) to diazoalkane (**100**) is a little tricky, since the methyl ester is also subject to saponification. It was found that addition of 4 equiv. of methanol to the 50% KOH/ether mixture, stirred rapidly in an ice–water bath, followed by addition of (**99**), gave optimal yields (30–40%) of (**100**).[129] The reaction mixture must be kept at ice temperature, as warming leads to emulsification and yield loss.

### 1.4.5.5 Aryldiazoalkanes

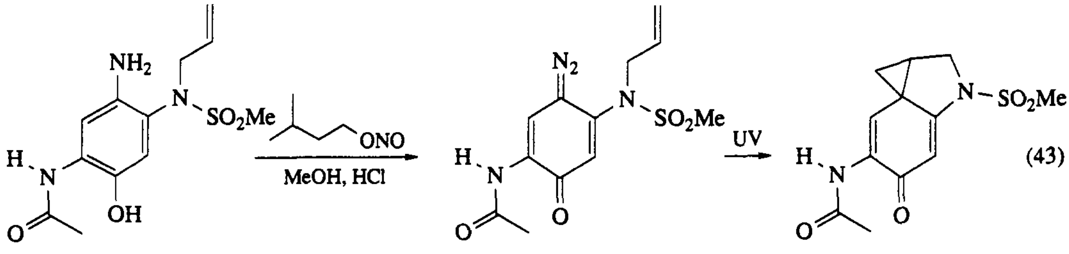
Aryldiazoalkanes are readily prepared by exposure of the arenesulfonylhydrazone to base (Bamford–Stevens reaction).[131] On addition of sodium methoxide, for instance, to a suspension of 1-naphthaldehyde tosylhydrazone (**101**) in methanol, the solid dissolves, and the solution turns red (equation 42).[132] The diazoalkane (**102**) can be isolated, as a pink-red solid, by dilution with water, extraction with pentane, drying ($Na_2SO_4$) and vacuum concentration. Naphthyldiazomethane reacts readily with acids to give the corresponding esters, which have the advantage, for chromatographic purification or analysis, of being UV-absorbing. An aryldiazoalkane can also be easily prepared by $MnO_2$ oxidation of the hydrazone of the corresponding ketone or aldehyde.[133]



(101) (102) (42)

### 1.4.5.6 Quinone Diazides

Quinone diazides such as **(104)** are readily prepared by nitrosation of 4-aminophenols.[134] On photolysis, **(104)** smoothly cyclizes to **(105)**, a model for the antitumor antibiotic CC-1065 (equation 43).[135]



(103) (104) (105) (43)

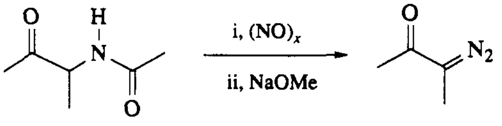
## 1.4.6 PREPARATION OF α-DIAZO KETONES AND ESTERS

It has not been fully appreciated that α-diazo ketones and esters are easily purified and are quite stable. In the past, such derivatives have been primarily expensive research intermediates. Now, with much better methods available for their preparation, these simple stabilized ylides deserve serious consideration as synthetic intermediates, even on an industrial scale.

### 1.4.6.1 Acyclic α-Diazo Ketones

#### *1.4.6.1.1 From α-amino ketones*

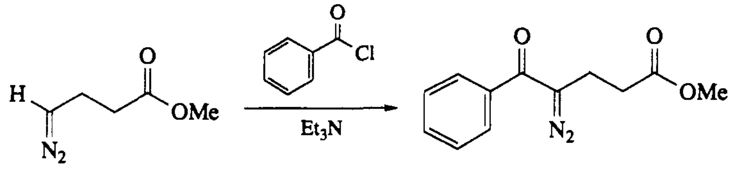
Acylated or sulfonylated α-amino ketones such as **(106)** are smoothly converted *via N*-nitrosation to the corresponding α-diazo ketones (**107**; equation 44).[136] A limitation to this approach has been the difficulty of preparing precursors such as **(106)**, especially given the instability of the precursor α-amino ketones. A recent report that an azide is smoothly converted to the corresponding carboxamide on exposure to triethylphosphine and a carboxylic acid might nicely sidestep this difficulty.[137]



(106) (107) (44)

#### *1.4.6.1.2 From diazoalkanes*

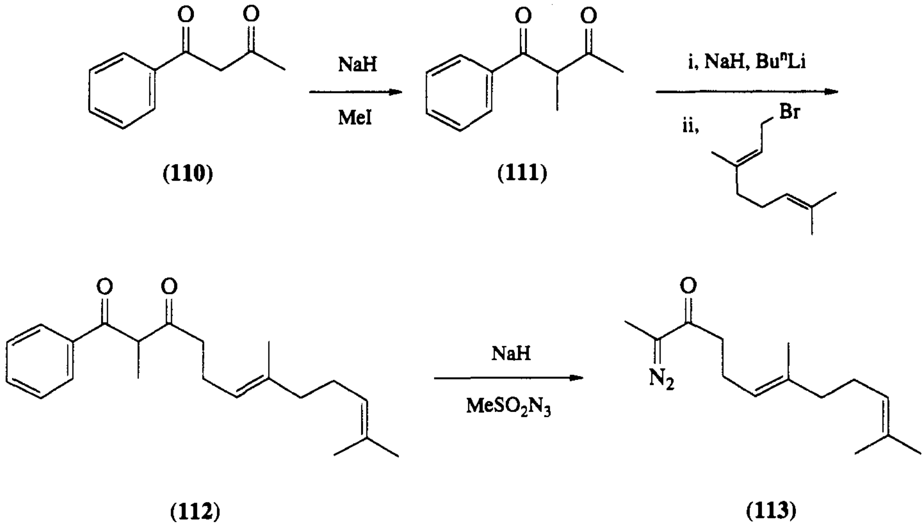
A diazoalkane **(108)** will couple smoothly with an acid chloride or a mixed anhydride to give the corresponding α-diazo ketone (**109**; equation 45).[138] A limitation on this approach is the difficulty of preparing and handling the requisite diazoalkanes (Section 1.4.5.4). Unlike the diazoalkanes, the product α-diazo ketones are stable to silica gel chromatography, and are readily purified.



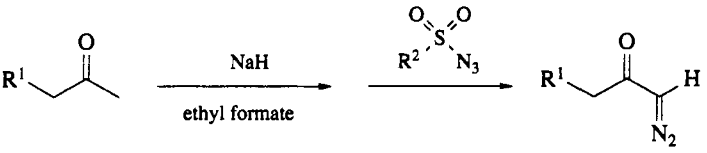
**(108)** **(109)** (45)

### *1.4.6.1.3 By diazo transfer/cyclization*

Diazo transfer from a sulfonyl azide is well known as a method for the preparation of α-diazo active methylene compounds (see Section 1.4.6.4). Application of this method to an α-alkylated 1,3-diketone leads, *via* fragmentation, to the simple α-diazo ketone. As illustrated for (**112**; Scheme 25) fragmentation can be highly chemoselective, so an unsymmetrical diketone can give a single product. The dianion alkylation approach outlined in Scheme 25 is currently the method of choice for preparing practical quantities of simple α-diazo ketones.[139] It should be noted that the sequence dianion alkylation/diazo transfer is most efficiently carried out in the same reaction vessel. A diazomethyl ketone (**115**) can also be prepared by diazo transfer. Thus, formylation of a methyl ketone (**114**) is usually highly regioselective (equation 46). Addition of a sulfonyl azide to the formylation mixture gives directly the diazomethyl ketone.[140]



**Scheme 25**

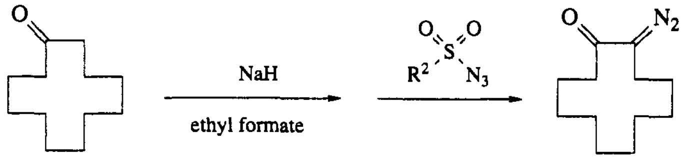


**(114)** **(115)** (46)

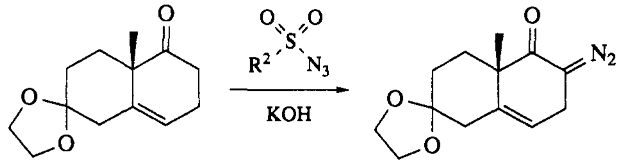
## 1.4.6.2 Cyclic α-Diazo Ketones

Usually, a cyclic α-diazo ketone such as (**117**) is prepared by formylation/diazo transfer (equation 47).[141] Such diazo ketones can also be prepared by phase transfer reaction of the parent ketone with

2,4,6-triisopropylbenzenesulfonyl azide, as illustrated for the conversion of (**118**) to (**119**) (equation 48).[142]



(**116**) (**117**) (47)

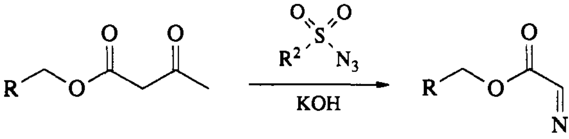


(**118**) (**119**) (48)

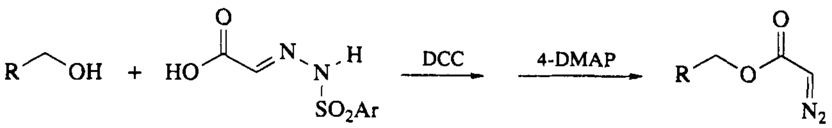
### 1.4.6.3 α-Diazo Esters

#### *1.4.6.3.1 Esters of diazoacetic acid*

Two strategies have been developed for the preparation of esters of diazoacetic acid. If the alcohol is inexpensive, it is first converted (diketene) into the corresponding acetoacetate (**120**; equation 49). Diazo transfer with subsequent deacylation then yields the diazoacetate (**121**).[143] If the alcohol is particularly valuable or sensitive, it may alternatively be esterified with a more direct precursor to diazoacetate. One reagent that has been used for this purpose is glyoxalic acid 2,4,6-triisopropylbenzenesulfonylhydrazone (TIPPS) (**123**; equation 50). Esterification of the alcohol (**122**) with (**123**), using dicyclohexylcarbodiimide followed by addition of 4-dimethylaminopyridine, gives the diazoacetate (**124**).[144]



(**120**) (**121**) (49)

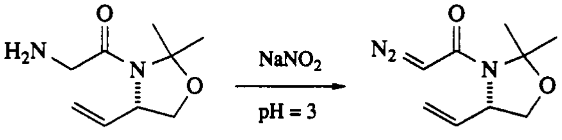


(**122**) (**123**) (**124**) (50)

#### *1.4.6.3.2 Higher α-diazo esters*

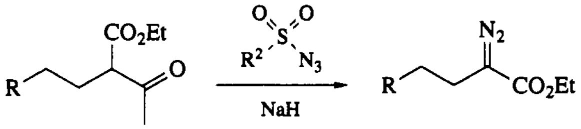
As with diazo ketones, an α-diazo ester (**126**) can be prepared by nitrosation of the corresponding α-amino acid (**125**) or a derivative (equation 51).[145] Alternatively, an α-diazo ester (**128**) can be prepared by diazo transfer to an alkylated acetoacetate (**127**), with concomitant deacylation (equation 52).[139]

To prepare an α-diazo ester from the ester (**129**) itself, formylation is effective. Alternatively, it has been reported that trifluoroacetylation of an ester proceeds smoothly (equation 53).[146] The trifluoromethylacetoacetate (**130**) would be expected to react directly with methanesulfonyl azide and sodium hydride to give the α-diazo ester.



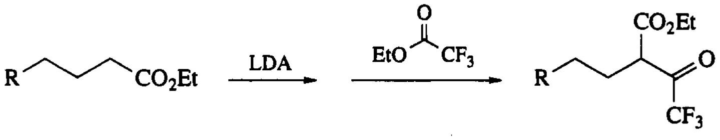
(125) (126)

(51)



(127) (128)

(52)



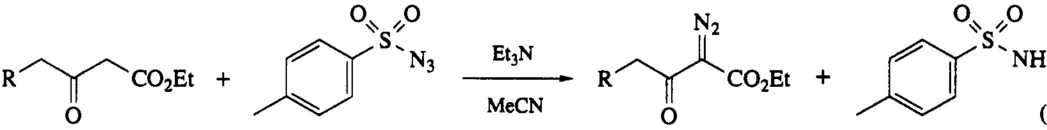
(129) (130)

(53)

## 1.4.6.4 Diazo Transfer to Active Methylene Compounds

### *1.4.6.4.1 Diazo transfer to β-keto esters*

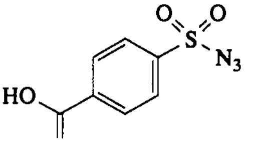
The original Regitz procedure for diazo transfer to a β-keto ester (**131**) used *p*-toluenesulfonyl azide (**132**; equation 54).[143] This reagent works well, and is easy to prepare from the corresponding sulfonyl chloride. A disadvantage of this reagent is that the *p*-toluenesulfonylamide coproduct (**134**), as well as any excess *p*-toluenesulfonyl azide, have to be removed from the product diazo ketone (**133**) before it can be used.



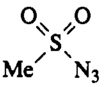
(54)

(131) (132) (133) (134)

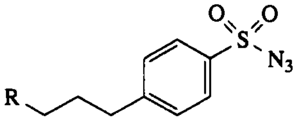
Several alternative sulfonyl azides have been used. Hendrickson introduced *p*-carboxybenzenesulfonyl azide (**135**).[147] Both the coproduced sulfonamide and any excess reagent are readily extractable by aqueous base, so product clean-up is easy. One limitation is that the starting sulfonyl chloride is somewhat expensive. Methanesulfonyl azide is much less expensive, yet still offers the same advantage, that the coproduced sulfonamide and excess reagent are readily removed by extraction with aqueous base.[141] Caution is, however, warranted, since methanesulfonyl azide is potentially explosive. Finally, advantage can be taken of the particular product being prepared. In the Merck thienamycin process, for instance, a lipophilic arenesulfonyl azide (**137**) is used. The product diazo ketone, a polar, highly crystalline β-lactam, is easily separated from this reagent and its coproducts.[148]



(135)



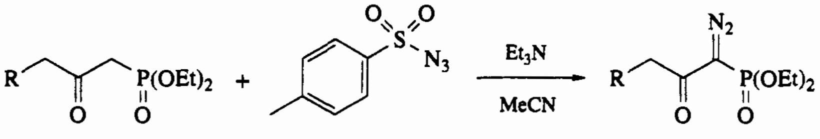
(136)



(137)

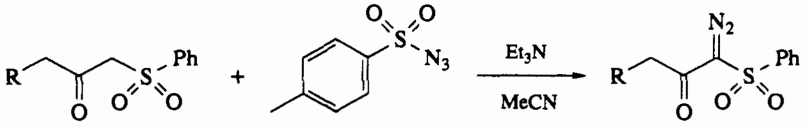
#### *1.4.6.4.2 Diazo transfer to other active methylene compounds*

Malonate esters and vinylogous malonates,[149] as well as 1,3-diketones, readily undergo diazo transfer. In addition, the less acidic β-keto phosphonates (**138**; equation 55)[150] and β-keto sulfones (**140**; equation 56)[151] have been shown to participate in this reaction.



(55)

**(138)** **(139)**



(56)

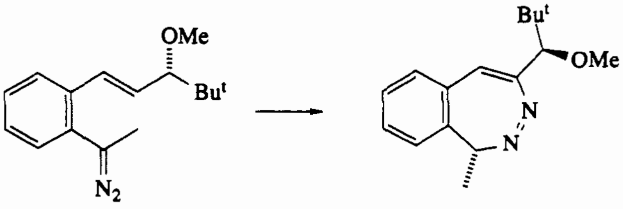
**(140)** **(141)**

## 1.4.7 SYNTHETIC APPLICATIONS OF DIAZO COMPOUNDS

Many of the reactions of diazo compounds are covered in detail elsewhere in these volumes. The attempt made here is to briefly highlight the diverse reactivity of the diazo functional group.

### 1.4.7.1 Dipolar Cycloaddition

Diazoalkanes undergo smooth 1,3-dipolar cycloaddition. For additions to simple alkenes, this is presumably an electrophilic process. In the example illustrated, the overall process of electrocyclization of (**142**) followed by hydride shift proceeds with remarkable diastereoselectivity (equation 57).[152]

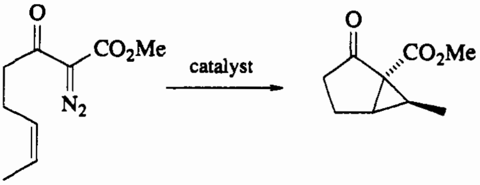


(57)

**(142)** **(143)**

### 1.4.7.2 Alkene Insertion to Make Cyclopropanes

An α-diazo ketone or ester such as (**144**) will, *via* metal-mediated nitrogen loss, insert into an alkene to make the corresponding cyclopropane (**145**; equation 58).[153,154] As illustrated, alkene geometry is retained, as would be expected for a concerted process. Cyclopropane construction by diazo insertion is reviewed in detail elsewhere in these volumes.

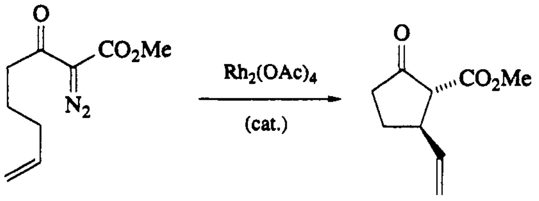


(58)

**(144)** **(145)**

### 1.4.7.3 C—H Insertion

An α-diazo ketone or ester such as (**146**) can also, *via* metal-mediated nitrogen loss, undergo 1,5 C—H insertion, to make the corresponding cyclopentane (**147**; equation 59).[155] This process, most efficiently catalyzed by $Rh^{II}$ dimers, is also reviewed in detail elsewhere in these volumes. It is striking that with copper bronze catalyst, (**146**) gives only intramolecular cyclopropanation.[156]

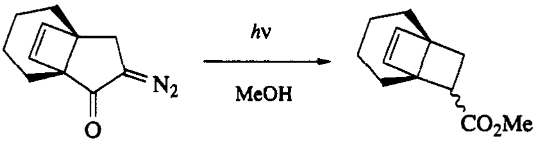


(**146**) (**147**)

(59)

### 1.4.7.4 Wolff Rearrangement/Arndt–Eistert Synthesis

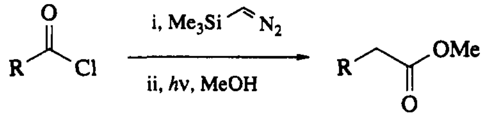
On UV irradiation, an α-diazo ketone such as (**148**), prepared in this case from the parent ketone by formylation/diazo transfer, rearranges with loss of nitrogen to the corresponding ketene (equation 60).[157] In methanol solvent, the methyl ester (**149**) is the product. In aqueous dioxane, the product is the carboxylic acid. It should be noted that substrate (**146**; equation 59), on UV irradiation, gives only the product of Wolff rearrangement, with little trace of either (**147**) or the corresponding cyclopropane.[158] This is significant evidence that both of these latter products are derived from transient organometallic intermediates.



(**148**) (**149**)

(60)

A straight chain diazomethyl ketone will also undergo Wolff rearrangement on irradiation. Such diazomethyl ketones are readily prepared from the corresponding acid chloride (**150**) by exposure to diazomethane or, more conveniently, trimethylsilyldiazomethane (Petrarch).[159] The net one-carbon homologation so effected is known as the Arndt–Eistert synthesis.



(**150**) (**151**)

(61)

### 1.4.7.5 Hetero-H Insertion

$Rh^{II}$-mediated hetero-H insertion may proceed by initial coordination of the intermediate metal–carbene complex with the nonbonding electrons of the heteroatom. Proton transfer would then give the observed product. This can be an efficient process both for forming C—N bonds, as in the cyclization of (**152**; equation 62),[148] and for C—O bonds, as illustrated by the construction of ether (**155**; equation 63).[160] Si—H insertion of (**156**) was shown to proceed with retention of absolute configuration, as would be expected for a concerted transition metal carbene mediated process (equation 64).[161]

The reactions illustrated in equations (62–64) are each catalyzed by rhodium acetate. Diazo compounds, especially diazoalkanes, can also react by a simple ionic mechanism. The esterification of a carboxylic acid with diazomethane is a familiar example. The ionic pathway is especially likely when the intermediate carbocation would be stabilized. Thus, diazine (**158**) couples smoothly with phenols, presumably by thermal rearrangement to the corresponding diazo sugar, followed by acid-catalyzed $N_2$ loss

## 1.4.7.6 Ylide Formation

In the examples illustrated above (equations 62–64), the heteroatom had an attached proton, which transferred readily. In the absence of such a proton, the initially-formed ylide can undergo other reactions. One of the more interesting of these is 1,3-dipolar cycloaddition, as illustrated by the conversion of (**160**) to (**161**) (equation 66).[163] Rhodium-mediated diazo addition to an ether is currently the method of choice for preparing such oxonium ylides.

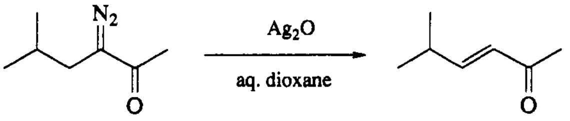
(161)

(66)

## 1.4.7.7 Elimination to Make Alkenes

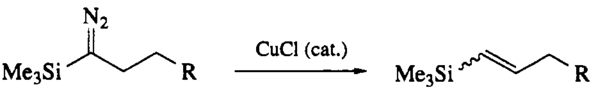
In 1957, Franzen reported that $Ag_2O$ catalyzes the transformation of an α-diazo ketone (**162**) to the corresponding enone (**163**; equation 67).[134] Regitz later made the intriguing observation that for cyclic α-diazo ketones, at least a seven-membered ring is required for efficient conversion to the enone, suggesting that conformational effects may be important.[164] Holt showed that other metallic salts catalyze this transformation, although not as effectively as silver oxide or silver nitrate.[165]



(67)

**(162)** **(163)**

A silyldiazoalkane (**164**) is converted to the alkene (**165**) under $Cu^I$ catalysis. The silyldiazoalkane (**164**) was prepared by deprotonation and alkylation of trimethylsilyldiazomethane.[166]

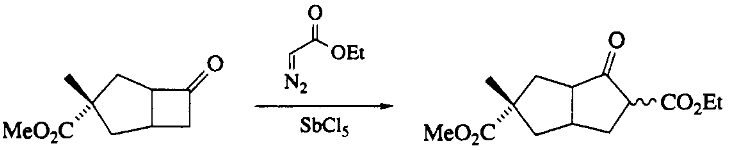


(68)

**(164)** **(165)**

### 1.4.7.8 Homologation of Ketones and Aldehydes

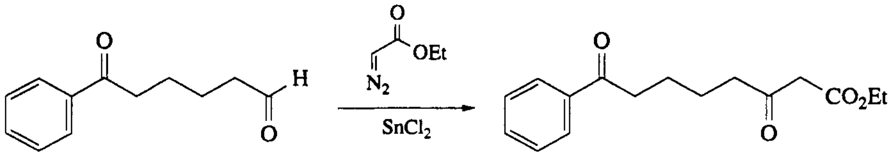
A diazo ester or alkane will react with a ketone, under Lewis acid catalysis, to give the homologated product. This reaction is most often used for one-carbon ring expansion, as illustrated by the conversion of (**166**) to (**167**; equation 69).[167] The regioselectivity of the (**166**) to (**167**) transformation, 98:2 in the example illustrated, was found to depend on both the diazoalkane and the Lewis acid used. With diazomethane and boron trifluoride, a 1:1 mixture of regioisomeric products was observed.



(69)

**(166)** **(167)**

This homologation reaction most likely proceeds *via* nucleophilic addition of the diazo compound to the Lewis acid complexed carbonyl, followed by 1,2-alkyl migration with concomitant loss of $N_2$. Application of this reaction to an aldehyde (**168**) gives, *via* 1,2-hydride shift, the corresponding β-keto ester (**169**; equation 70).[168]



(70)

## 1.5.1 INTRODUCTION

During the 1980s, organic sulfur compounds have become increasingly useful and important in organic syntheses. Sulfur incorporated into an organic molecule activates, by its electronegativity, the hydrogen atoms situated on the adjacent carbon atom, increasing their thermodynamic acidity. The acidity of a proton α to a sulfoxide group or to a sulfone group falls between those of a benzylic proton and a proton α to a carboxylate function. It has been demonstrated that sulfur groups exert stabilizing effects on the corresponding carbanions that are much larger than those expected from their polar contributions.[1] The stabilizing resonance effect for the phenyl sulfone group was estimated to be equivalent to 33–75 kJ $mol^{-1}$ (8–18 kcal $mol^{-1}$), which is comparable with that of a cyano group but somewhat smaller than that of carbonyl or nitro functions. No data are available for a sulfoxide group and, to our knowledge, the extent of such acidification in β-keto sulfoxides or related compounds has not yet been determined. Another report[2] also showed that the presence of a phenylthio group increases the acidity of cyclohexanone by at least 3 p*K* units, corresponding to a stabilizing effect of the order of 25–42 kJ $mol^{-1}$ (6–10 kcal $mol^{-1}$).[3] This stabilizing effect was attributed to conjugative effects or polarization effects[4] involving the 3*d*-orbitals of sulfur.

The variety of sulfur compounds generating such carbanion structures permitted the development of several synthetic methods for carbon–carbon bond formation.

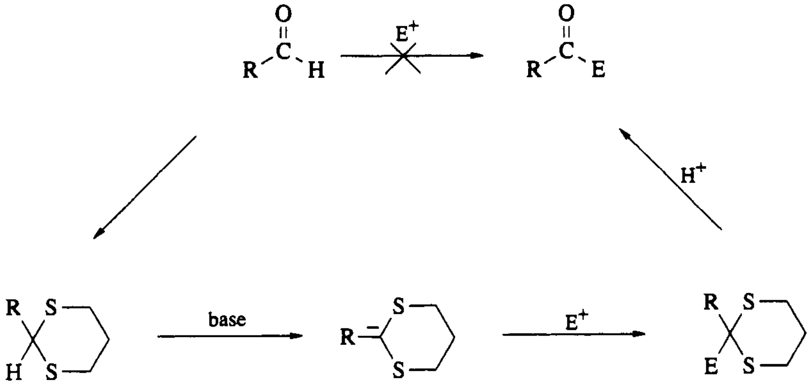
The basic chemistry of organosulfur compounds has already been reviewed in depth in 'Comprehensive Organic Chemistry',[5] so the purpose of this chapter is to outline the important developments in the use of sulfur-containing reagents in organic syntheses since the reviews cited in refs. 6 and 7, which appeared in 1978, were published.

Because of the large variety of sulfur compounds, this chapter will be limited to thioacetals, sulfides, sulfoxides and sulfones. Many examples, selected from recent total syntheses of natural products, will emphasize the selectivity (chemo-, regio-, diastereo- and enantio-selectivity) of these reactions.

## 1.5.2 SULFIDES

### 1.5.2.1 Thioacetals

Among organic sulfides, those derived from 1,3-dithiane occupy an important place. The interest in these reagents lies not only in their reactivity with electrophilic substrates but also in the synthetic principles which have been developed from work on these compounds. By masking the aldehyde group by the formation of a dithiane, the carbon atom may participate in nucleophilic additions or substitution reactions and after hydrolysis of the thioacetal, the carbonyl group can then be regenerated (Scheme 1).



**Scheme 1**

Overall an inversion of polarity of the carbonyl group can thus be achieved; this principle was called 'umpolung' by Seebach.[8] We owe to Corey and Seebach the use of the anions of dithiane, which are more stable than those of noncyclic thioacetals.[9] Although this question was reviewed by Seebach[10] and also by Durst in 'Comprehensive Organic Chemistry',[11] we will briefly comment on the main reactions of the dithiane group.

Dithianes may be prepared by the action of propanethiol on aldehydes or ketones or their acetals in chloroform in the presence of boron trifluoride.[12]

The action of *n*-butyllithium in THF at low temperature leads to the anion. After reaction with an electrophilic compound, the hydrolysis can generally be carried out in polar solvents (acetone, alcohols, acetonitrile) in the presence of mercury(II) chloride or oxide and water.[12–14] In other cases, NBS,[14,15] chloramine T,[16] cerium(IV) ammonium nitrate,[17] *n*-tributyltin hydride,[18] trialkyloxonium tetrafluoroborate,[19] thallium nitrate[20] or photochemistry[21] can be used. Desulfurization by Raney nickel gives hydrocarbons.[22]

Typical examples of the reactions of carbanions α to dithiane are shown in Scheme 2.

Some noncyclic thioacetals are sometimes used for the preparation of keto acids from aryl halides[25] or keto esters[26] by 1,4-addition on α,β-unsaturated ketones (Scheme 3).

Ketene dithioacetals should also be mentioned; these are readily prepared by dehydrogenation of saturated dithioacetals,[27,28] or dihydrohalogenation of 2-dichloromethyl-1,3-dithiane followed by chain extension (Scheme 4).[29]

Wittig-type reactions have also been used to prepare ketene dithioacetals (Scheme 5).[30–36]

A variety of complex molecules have been synthesized by methods involving dithioacetal chemistry. Cyclophanediones have been generated by a sequence employing alkylation of the bisdithianyl derivative of isophthalaldehyde (Scheme 6).[37]

Alnusone, a biphenyl-type natural product, was also synthesized by using a dithianyl reagent to open an epoxide ring (Scheme 7).[38]

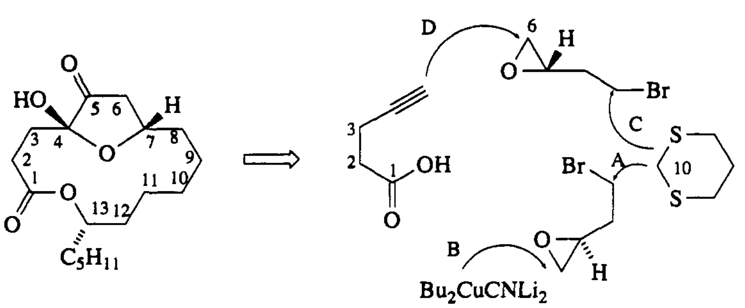
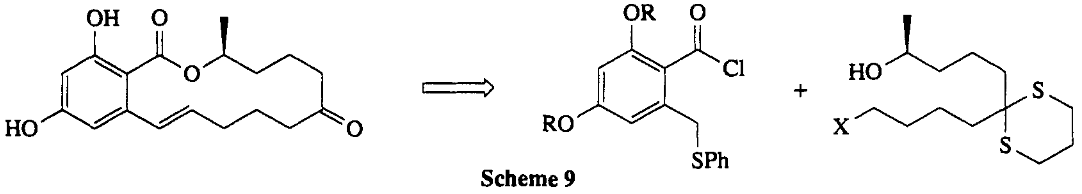
Another relevant example is the total synthesis of the macrolide glacosporone,[39] a germination self-inhibitor from the fungus *Colletotrichum glocosporioides*. The retrosynthetic scheme shows the important role played by the dithiane anion (Scheme 8).

Finally, the recent total synthesis of zearalenone reported by Rao[40] gives a good illustration of the range of reactions available for organosulfur compounds: the macrocyclization reaction, the formation of the double bond and the introduction of the ketone group were made possible by using sulfur-containing

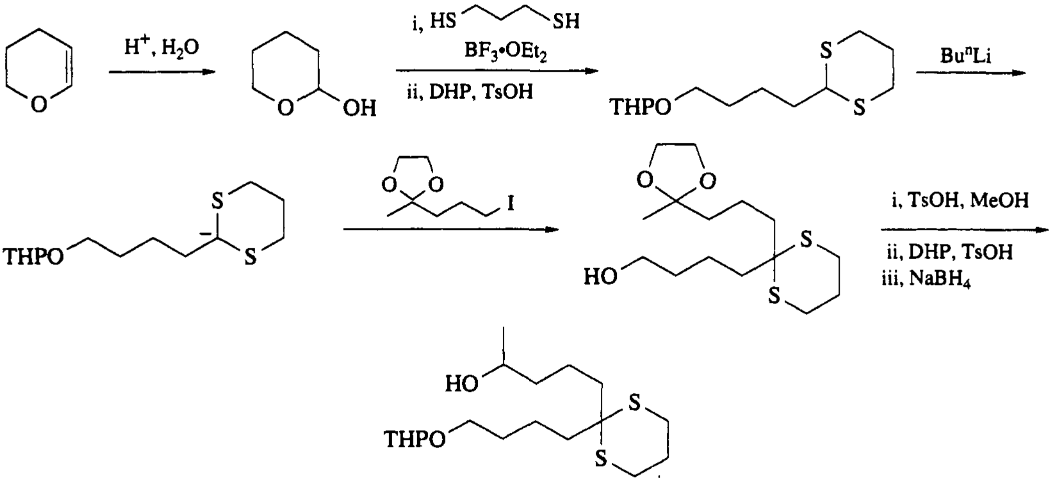


**Scheme 8**

reagents as shown on the retrosynthetic scheme (Scheme 9). The nonaromatic part of the molecule was readily made from dihydropyran *via* thioacetal formation from the corresponding hemiacetal, followed by alkylation of dithiane carbanion (Scheme 10).



**Scheme 9**

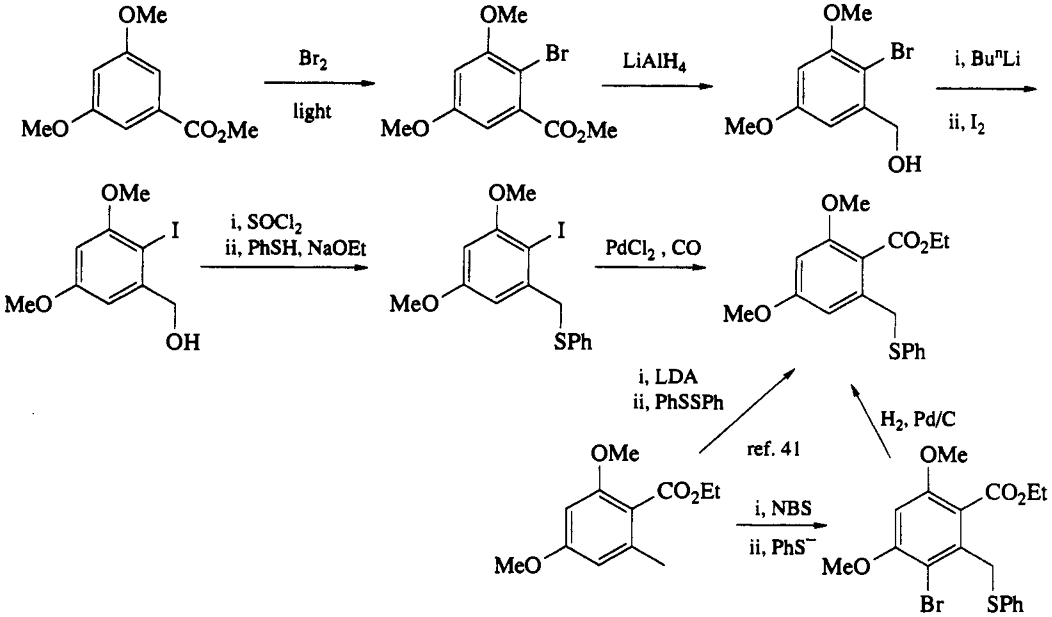


**Scheme 10**

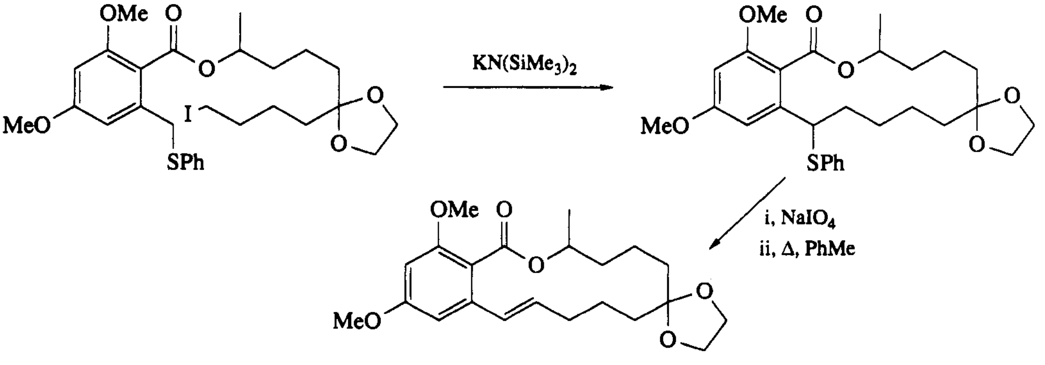
Although benzylic sulfides will be treated later in a separate section, the synthesis of zearalenone gives the first opportunity to mention their synthetic use. The introduction of sulfur to build the aromatic part of zearalenone was done in two different ways:[41,42] displacement of a benzylic bromide by benzenethiol or reaction of diphenyl disulfide with benzylic carbanion (Scheme 11).

Finally, zearalenone was obtained[43] by intramolecular alkylation of the carbanion α to the benzylic sulfide, which occurs readily with potassium hexamethyldisilazane. After cyclization, the double bond was created by oxidation of sulfide to sulfoxide followed by pyrolytic elimination, a technique described in more detail in the next section (Scheme 12).

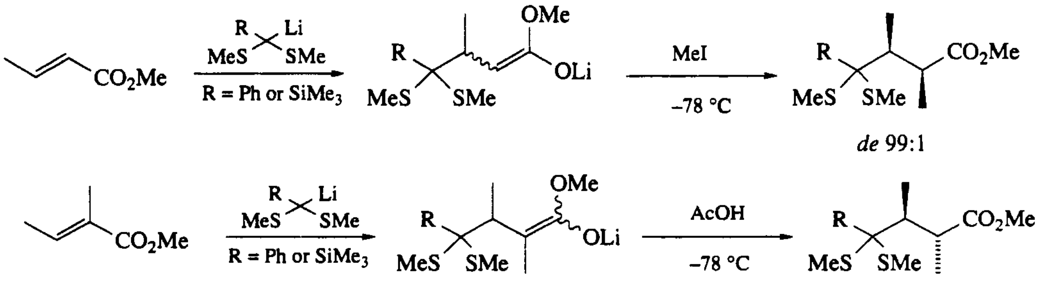
Recently, Koga[74] found a novel use of dithioacetal as a stereocontrolling unit during alkylation of acyclic α,β-unsaturated esters. Conjugate addition of lithiated dimethyl thioacetals to α,β-unsaturated esters in THF at low temperature, followed by subsequent methylation of the corresponding enolate gave only a single isomer. Alkylation and protonation take place with the electrophile attacking *anti* to the bulky dithioacetal for steric reasons (Scheme 13).



Scheme 11



Scheme 12



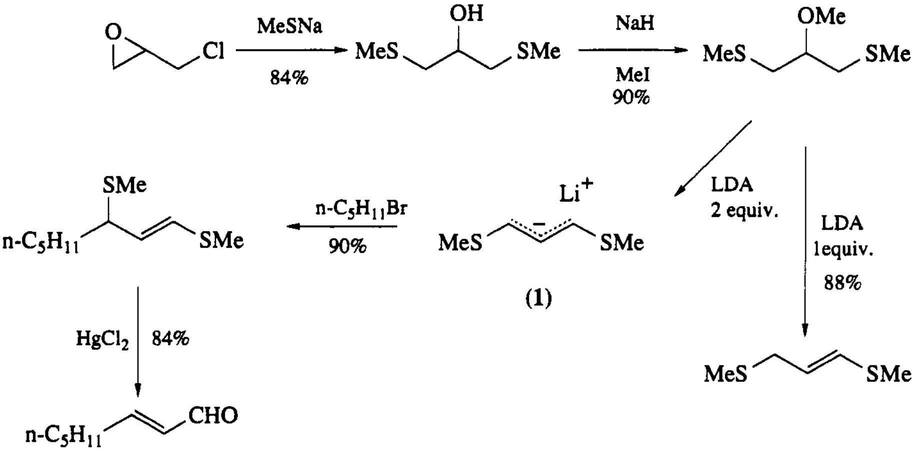
Scheme 13

## 1.5.2.2 Other Sulfides

Benzylic and allylic sulfides have very important applications in organic syntheses.

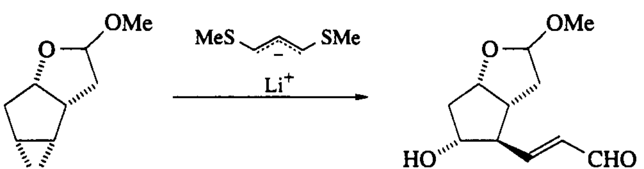
One of the first papers was published by Corey[44] on the use of bis(methylthio)allyllithium (**1**; Scheme 14) for the synthesis of α,β-unsaturated aldehydes from alkyl halides. The generation of the carbanion as the lithio derivative was readily accomplished by a simple three-step sequence from epichlorohydrin.

Reaction of epichlorohydrin with sodium methanethiolate gave 1,3-bis(methylthio)-2-propanol, which was converted to the sodio derivative and methylated to afford 1,3-bis(methylthio)-2-methoxypropane. Finally, treatment with LDA (1 equiv.) resulted in elimination of methanol to give 1,3-bis(methylthio)propene, whereas reaction with 2 equiv. of LDA gave bis(methylthio)allyllithium, which reacted with 1-bromopentane furnishing 1,3-bis(methylthio)-1-octene, which in turn was converted by hydrolysis with mercury(II) chloride to *trans*-2-octenal (Scheme 14).



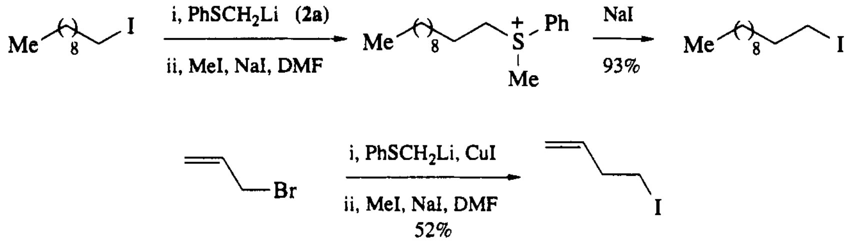
**Scheme 14**

The application of the lithio reagent (**1**) to the conversion of the oxidoacetal to the corresponding hydroxy aldehyde as a key step in a total synthesis of prostaglandin $F_{2\alpha}$ has been described (Scheme 15).[45]



**Scheme 15**

Phenylthiomethyllithium (**2a**) was used for the homologation of primary halides[46] in a two-step sequence: first halogen displacement by reagent (**2a**) or the organocuprate derivative (in the case of allylic compound) and then replacement of the phenylthio group by iodo by heating the sulfide with a large excess of methyl iodide in 1 M sodium iodide solution in DMF (Scheme 16).

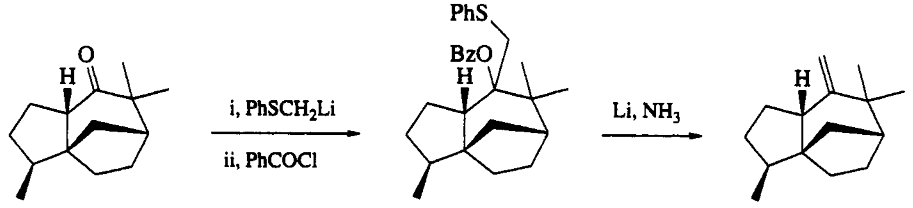


**Scheme 16**

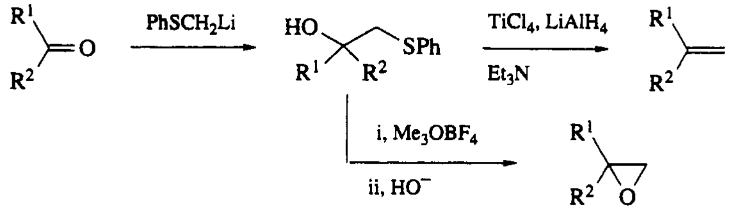
Phenylthiomethyllithium was also used for ketone methylenation,[47,49] mainly in the case of hindered ketones which do not react with the usual Wittig reagent. This is a three-step sequence: the reagent (**2a**) is added, then the resulting alcohol is acylated, and finally the exocyclic methylene is formed by reduction with lithium in ammonia (Scheme 17).

The phenylthiomethyl adduct could also be transformed in one step to methylene with $TiCl_4/LiAlH_4$[48] or to epoxide[50] *via* the corresponding sulfonium salt (Scheme 18).

α-Phenylthiomethyltrimethylsilane (**2b**) was shown to react with alkyl halides or epoxides giving in two steps the corresponding aldehyde.[51–53] This method is interesting because the α-phenylthioalkyl-

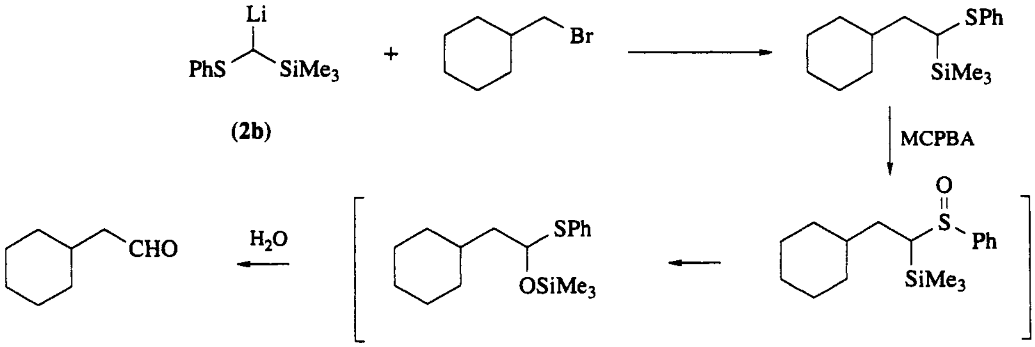


Scheme 17



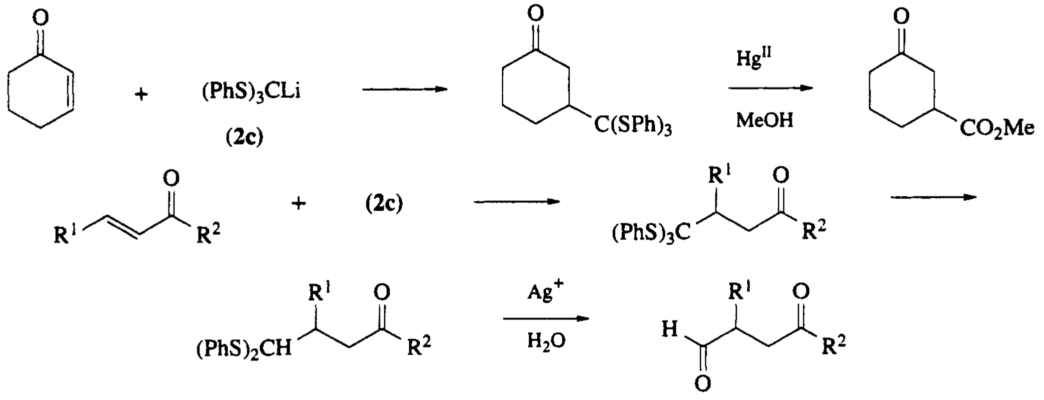
Scheme 18

trimethylsilane obtained in the first step can be oxidized to the corresponding sulfoxide, which undergoes a silyl-Pummerer rearrangement[54,55] giving an *O*-trimethylsilyl hemithioacetal, which is readily hydrolyzed to the aldehyde (Scheme 19).



Scheme 19

Tris(phenylthio)methyllithium (**2c**) adds in conjugate fashion to a number of enones,[56,57] and the resulting adduct could then be hydrolyzed into a carboxylic acid ester or aldehyde (Scheme 20).



Scheme 20

Michael addition of benzenethiolate to 4-*t*-butyl-1-cyanocyclohexene gives only products containing an axial $PhS^-$ group;[60] the same result was obtained from ethyl 4-*t*-butylcyclohexene-1-carboxylate.[61] In contrast, the addition of diethyl sodiomalonate gave only the equatorial malonate group under thermodynamic or kinetic control (Scheme 21).[58,59] Similar results were observed with the addition of tris(phenylthio)methyllithium (**2c**) on carvone.[62a]

**Scheme 22**

Chlorosulfides are often used for vicinal functionalization of alkenes. Silyl enol ethers can react with α-chloromethyl phenyl sulfides (**5**) in the presence of $ZnBr_2$[63] or $TiCl_4$[64] to give the corresponding β-keto sulfide, which could be easily transformed into the α-methylene ketone *via* sulfide oxidation to sulfoxide, followed by pyrolytic elimination (Scheme 23).

Cyclic α-chloro sulfides are easily made from the corresponding alkenes and PhSCl. They have also been reacted with *O*-silylated enolates or allyltrimethylsilanes (Scheme 24a).[65a] A stereoselective synthesis of α-chloro sulfide was also reported[65b] on a camphor derivative (Scheme 24b). A complete review on organic synthesis with α-chloro sulfides was recently published by McKervey.[66]

Recently Reetz[67] reported on the regio- and stereo-selective carbosulfenylation of alkenes.[67] When *trans*-β-chloro sulfides obtained from cyclic alkenes are allowed to react in a one-pot process with dimethylzinc in the presence of 20 mol % $TiCl_4$, the C—C coupling products are formed with complete retention of configuration. The same is true of noncyclic alkenes. The mechanism should probably proceed by the formation of an episulfonium ion, which is attacked by the complex $[MeTiCl_4]^-$ (Scheme 25).

Finally, the regioselectivity as well as the 1,2-asymmetric induction were investigated. In the case of optically active 2-methylcyclohexene the regioselectivity was 85%, giving mainly compound (**4**) with 99% diastereofacial selectivity (Scheme 26). For stereoelectronic reasons only (**3**) undergoes a *trans*-1,2-diaxial ring opening to give (**4**) in the chair conformation.

In the case of acyclic alkenes, the carbosulfinylations are likewise regio- and, depending on the nature of the protective group on oxygen, stereo-selective (large protecting groups give smaller 1,2-asymmetric induction; Scheme 26).

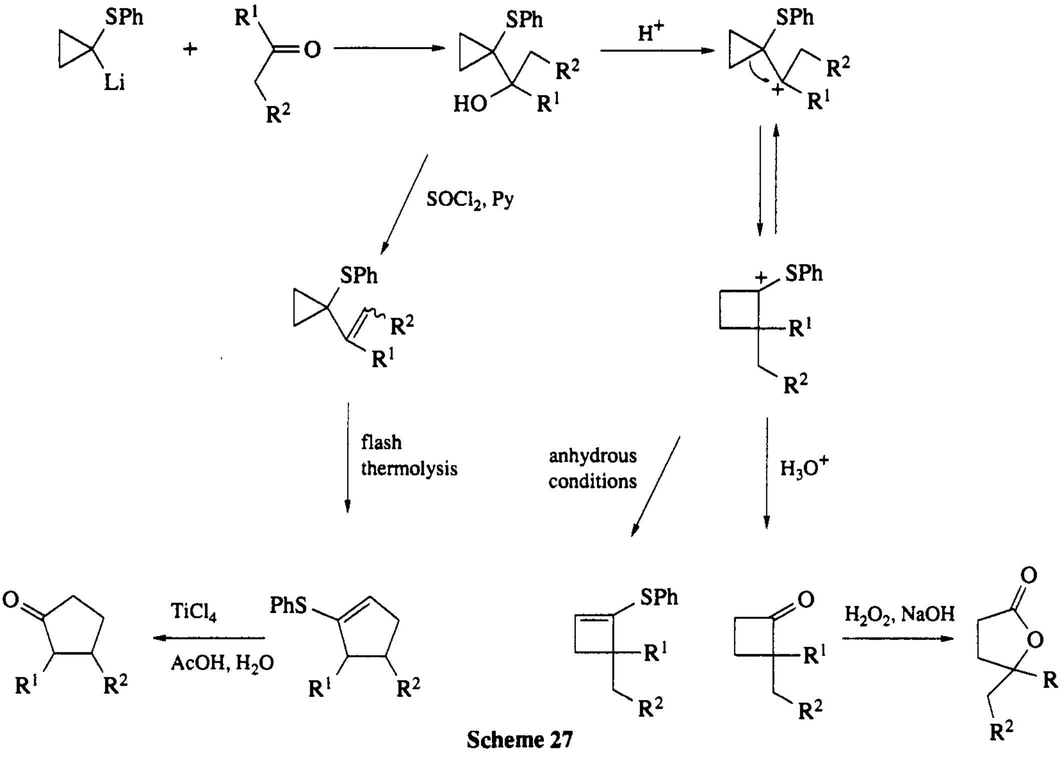
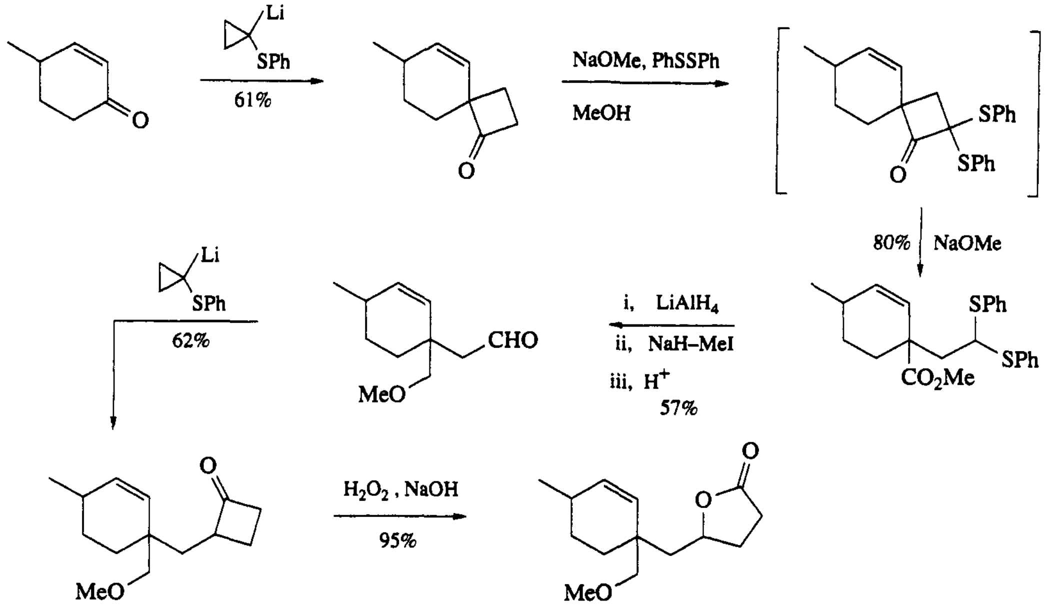
**Scheme 26**

Treatment of cyclopropyl phenyl sulfide with *n*-butyllithium gives α-lithio(phenylthio)cyclopropane, which reacts with electrophilic reagents to give adducts that undergo a variety of transformations, many of which are difficult to achieve by more conventional methodology. Perhaps the most interesting chemistry of cyclopropyl phenyl sulfide involves its reaction with carbonyl compounds,[68,69] giving cyclobutanones or 1-phenylthiocyclobutenes[70] through carbocation rearrangements. After dehydration of the adduct, the resulting vinylcyclopropane could be transformed into cyclopentanone by a known thermal rearrangement (Scheme 27).[71]



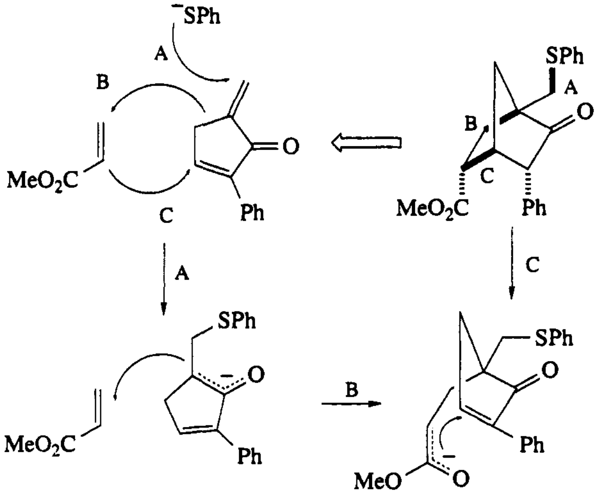
**Scheme 27**

Trost also found[72] that treatment of these cyclobutanones with sodium methoxide and diphenyl disulfide leads to *in situ* bisulfenylation and ring cleavage (secosulfenylation). This was applied to the total synthesis of verrucarol, a complex tetrahydrochromanone substituted at the ring junction by a hydroxymethyl substituent. The synthetic strategy[73] twice used the cyclobutanone formation from 1-lithiocyclopropyl phenyl sulfide and a ketone, followed by the secosulfenylation process and Baeyer–Villiger type rearrangement of cyclobutanone. Only this part of the synthesis is described in Scheme 28.



Scheme 28

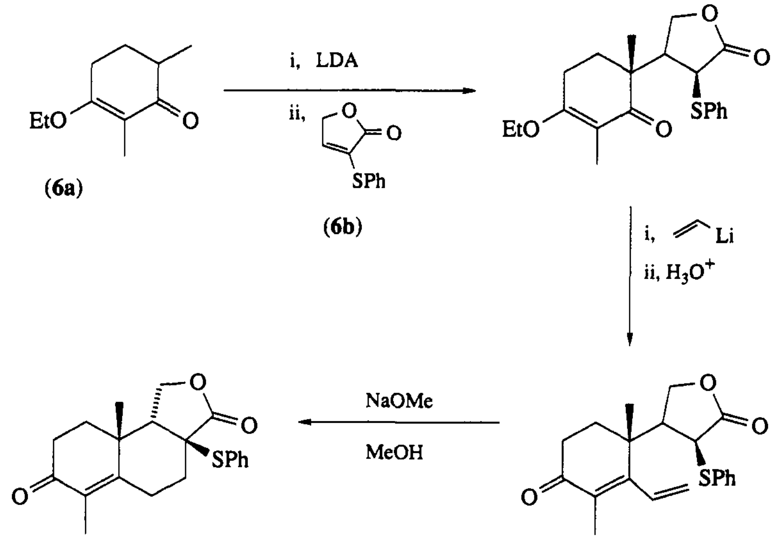
Sulfides were also involved in a unique three-component, stereospecific Michael addition.[75] The reaction described in Scheme 29 can be explained as follows: regiospecific addition of the nucleophile to the exocyclic double bond of the α-methylenecyclopentenone, followed by trapping of the resulting enolate by methyl acrylate, and attack of the anion thus formed on the endocyclic double bond of the cyclopentenone moiety to result, after protonation, in the bicyclo[2.2.1]heptan-6-one as a single stereoisomer (68% overall yield; Scheme 29).



Scheme 29

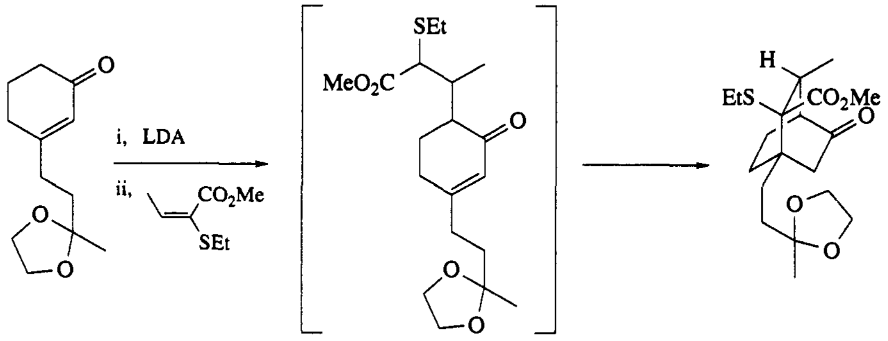
Sulfide has also been involved in a new two-step annulation method which featured stereospecific formation of three contiguous asymmetric centers.[76] It was found that the lithium dienolate of the vinylogous ester (**6a**) reacts rapidly with the α-thiophenyl butenolide (**6b**) to provide the corresponding adduct as a single diastereoisomer. Subsequent addition of vinyllithium, acidification and cyclization gave the tricyclic lactone (Scheme 30).

A similar highly stereoselective Michael addition has been reported by Uda.[77] The enolate of a substituted cyclohexenone reacted rapidly in a Michael-type addition with methyl α-thiophenylmethacrylate



Scheme 30

to provide the corresponding adduct, which, by an intramolecular Michael addition, leads to the substituted [2.2.2]octanone as a single stereoisomer (Scheme 31).



Scheme 31

Allylic sulfides can be coupled with allylic bromides in a process which was first described by Biellmann and applied to the squalene synthesis.[78] Farnesyl sulfide was prepared from 2,4-dinitrophenylfarnesyl oxide and benzenethiolate. Finally, the allylic thiocarbanion was coupled with farnesyl bromide to give, in 82% yield, squalene sulfide, easily transformed to squalene with Li/EtNH$_2$ (Scheme 32).

Several applications of this method appeared in the literature. Furaterpenes can be synthesized in this way; *e.g.* dendrolasin was made from *trans*-ω-chloroperillene and the carbanion of prenyl phenyl sulfide (Scheme 33).[79] Elemol has been synthesized by an intramolecular variant of Biellmann's method (Scheme 34).[80]

Until now, α-lithio ethers were nearly always prepared by deprotonation of an α-carbon atom of an ether having a special anion-stabilizing feature (carbonyl, cyano, phenylthio). An interesting report by Cohen[81] showed that a variety of types of unstabilized and stabilized α-lithio ethers can be readily prepared from α-(phenylthio) ethers by reductive lithiation with lithium 1-(dimethylamino)naphthalenide or lithium naphthalenide. What makes this method one of considerable generality is the ready availability of various types of α-(phenylthio) ether substrates or their vinylogues as shown in Scheme 35.

An example of this method is given by the synthesis of brevicomin.[81] The desired α-(phenylthio) ether (7) was made by Diels–Alder addition of phenyl vinyl sulfide and methyl vinyl ketone. Treatment of (7) with lithium 1-(dimethylamino)naphthalenide, followed by trapping of the anion with propionaldehyde and ring closure to an acetal during the acidic work-up, afforded a mixture of *endo* and *exo* isomers of brevicomin (Scheme 36).

Several other applications of this method have been published. Reductive lithiation of 1-(trimethylsilyl)cyclopropyl phenyl sulfide gives α-lithio(trimethylsilyl)cyclopropane, which reacts with carbonyl

compounds to give 1-(trimethylsilyl)cyclopropylethylenes. Pyrolysis of these compounds provides a new cyclopentane annulation procedure. A unique feature of this process is that the double bond in the vinylsilane is formed in the more highly substituted position (Scheme 37).[88]

The synthesis of (–)-β-selinene from the commercially available (–)-perillaldehyde used a reductive lithiation of 1-methoxycyclopropyl phenyl sulfide, condensation to an aldehyde, acid-catalyzed rearrangement to a vinylcyclobutanone and finally basic 1,3-sigmatropic rearrangement of the corresponding cyclobutanol to cyclohexenol (Scheme 38a).[89a] 1-Phenylthio-1-(trimethylsiloxy)cyclopropane was prepared *via* the silyl-Pummerer rearrangement with high stereoselectivity (Scheme 38b).[89b] (1-Methoxy-1-phenylthio)cyclopropane was also obtained from alkenes *via* Pummerer rearrangement.[89c] 2-Methoxy-3-phenylthiobuta-1,3-diene was also shown to be a novel annelating agent *via* a Diels–Alder reaction (Scheme 38c).

## 1.5.3 SULFOXIDES

This part concentrates mainly on the utility of chiral sulfoxides in asymmetric synthesis. The main advantage of sulfoxides over the other sulfur functions which are described in this review is indeed their chirality. Sulfoxides are chiral groups which are easy to introduce, easy to remove and give high asymmetric induction in many reactions.[90]

The best way to prepare large quantities of optically active sulfoxides makes use of optically active menthyl sulfinate. By esterification of *p*-toluenesulfinic acid with l-menthol, a mixture of diastereoisomeric menthyl sulfinates is obtained. This esterification reaction shows no particular stereoselectivity and therefore a mixture of the two diastereoisomeric esters was obtained. However, it is possible to equilibrate these diastereoisomers in acidic media and to shift the equilibrium towards the less soluble isomer, (–)-(*S*)-menthyl *p*-toluenesulfinate, which was obtained in 90% yield from the starting *p*-toluenesulfinic acid (Scheme 39).[91]

Scheme 39

Optically active sulfoxides are readily obtained from menthyl sulfinate by a Grignard reaction. This reaction was originally proposed by Gilman[92] and applied to optically active products by Andersen:[93,94] this is a pure $S_N2$ reaction at sulfur with displacement of the menthoxy group by the Grignard. A great variety of sulfoxides have been prepared by this method;[90,95–105] other organometallics have also been used. A few examples are shown in Scheme 40.

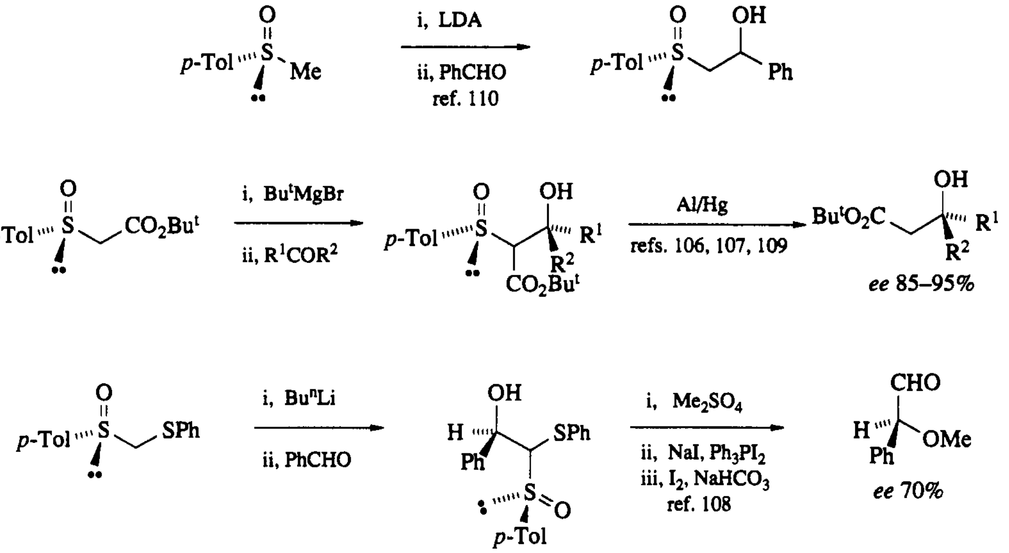
Scheme 40

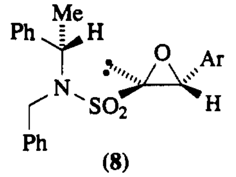
If optically active sulfoxides such as methyl *p*-tolyl sulfoxide give a poor diastereoselectivity when such an α-sulfinyl carbanion is added to a carbonyl,[90] the presence of another function such as ester, sulfide or amide, which has a chelating effect in the transition state, makes optically active α-sulfinyl esters, sulfides or amides very useful in asymmetric aldol-type condensation (Scheme 41).[97,106–109]



**Scheme 41**

Optically active sulfoxides can also be prepared by asymmetric oxidation of sulfides. However, numerous papers have reported very low enantioselectivity.[111] Only one report,[112–113] using a modified Sharpless reagent, $H_2O/Ti(OPr^i)_4$/diethyl tartrate/$Bu^tOOH$, described asymmetric oxidation of alkyl aryl sulfoxides with good enantiomeric excesses: 75 to 95%.

It should also be mentioned that optically active 2-sulfamyloxaziridines (**8**) afforded high asymmetric induction[114a] for the oxidation of nonfunctionalized sulfides to sulfoxides (53–91% *ee*). The enantioselectivities exhibited by these reagents are comparable to, or in some cases better than, the modified Sharpless reagent reported by Kagan.



(**8**)

Several papers have also reported asymmetric oxidation of chiral sulfides having a structure derived from camphor.[114b,c]

Optically active vinylic sulfoxides can be prepared by the Andersen synthesis, using (–)-menthyl (–)-(*S*)-*p*-toluenesulfinate and vinylic Grignards,[115,116] or by the Wittig–Horner procedure, using carbonyl compounds and the anion of dimethyl (*R*)-*p*-toluenesulfinylmethanephosphonate, easily made from the corresponding menthyl sulfinate.[117] However, applicability of the former method depends on the availability of stereochemically pure 1-alkenyl halides for preparing Grignard reagents and the latter usually leads to a mixture of (*E*)- and (*Z*)-vinylic sulfoxides. Therefore, it is sometimes easier to prepare the corresponding alkynyl sulfoxide by the Andersen method from alkynyl Grignards and then reduce stereospecifically the triple bond into a *trans* double bond with DIBAL or a *cis* double bond by catalytic hydrogenation using the Wilkinson catalyst (Scheme 42).[118,119]

Vinylic sulfoxides have been used successfully in several Michael-type asymmetric syntheses.[120–124] One typical example is given by the asymmetric synthesis of (–)-methyl jasmonate (Scheme 43).[123]

The CD rings of steroids were synthesized by the same method in high enantiomeric purity.[124]

Vinylic sulfoxides have also been used in asymmetric Diels–Alder reaction.[125–130] A very high diastereoselectivity was observed with optically active sulfinylacrylates. One example[126] is given in Scheme 44.

An interesting observation was reported by Posner who showed that α-pyrone substituted by a sulfoxide[131] or a sulfone[132] reacts rapidly with vinyl ethers, giving a diastereoselective [2 + 4] cycloaddition (Scheme 45). Racemic sulfide, sulfoxide or sulfone was introduced on α-pyrone *via* 3-cuprio-

They can also be used as vinylic carbanion species as shown by the asymmetric synthesis of the chroman ring of vitamin E.[137] The (*E*)/(*Z*) mixture of chiral sulfoxide (**9**) was readily isomerized into the (*E*)-isomer with LDA in THF (the exclusive formation of the (*E*)-isomer was due to the chelation of lithium with an oxygen of the acetal). Condensation to trimethylhydroquinonecarbaldehyde gave only one diastereoisomer and then the cyclization in presence of sodium methoxide was also fully stereoselective (the stereochemistry of the cyclization being controlled by that of the allylic hydroxy group which is eliminated during the cyclization; Scheme 48).

A few other examples are listed in Scheme 49: intramolecular addition of amine giving a good synthesis of (*R*)-(+)-carnegine,[138] synthesis of chiral butenolides by carbonation of vinylic carbanions[139] and conjugate additions of cuprates yielding chiral chromans.[140]

Allylic sulfoxides are also of interest mainly because of the possible sulfoxide/sulfenate rearrangement described by Mislow[141] when he observed that allyl *p*-tolyl sulfoxide racemized in a temperature range

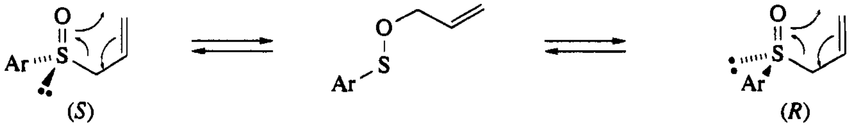
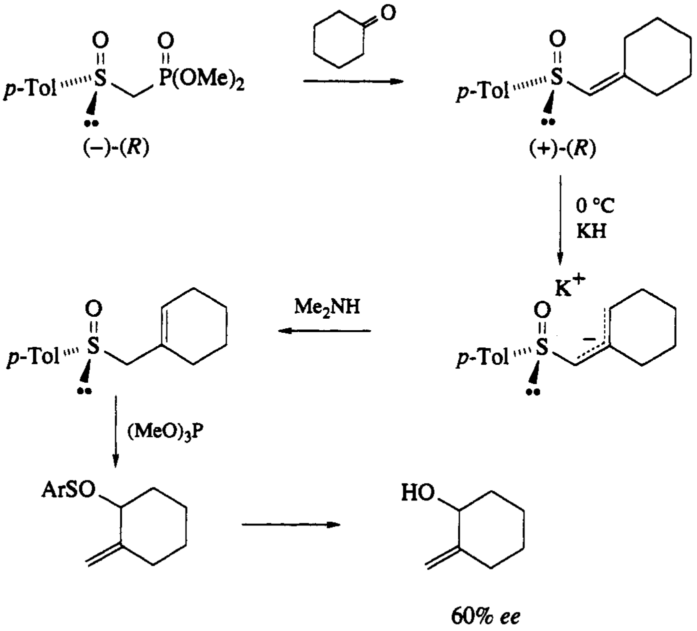
(50–70 °C) significantly below the usual racemization temperature of sulfoxides (150 °C and higher; Scheme 50).



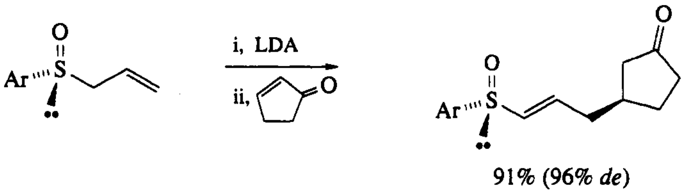
Scheme 50

This 2,3-sigmatropic shift has been of substantial utility since Evans[142] and Hoffmann[143] realized that allyl alcohols can be obtained by intercepting the sulfenate with thiophilic agents. One possible way of preparing optically active allylic sulfoxides, which started to racemize even at 0 °C was the isomerization of the corresponding vinylic sulfoxide followed by the sulfenate rearrangement in the presence of trimethyl phosphite (Scheme 51).[143,144]



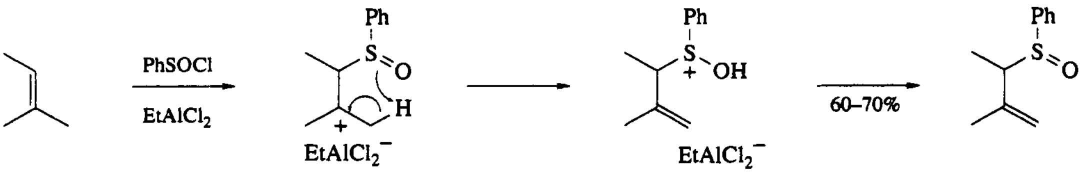
**Scheme 51**

The carbanions of allylic sulfoxides undergo kinetically controlled conjugate additions to give vinylic sulfoxides as a single diastereoisomer (Scheme 52).[145,146]



**Scheme 52**

(*E*)- and (*Z*)-allylic sulfoxides bearing alkyl groups at C-3 also undergo highly stereoselective conjugate additions to cyclic enones to give *syn*- and *anti*-vinylic sulfoxides.[146c] Racemic allylic sulfoxides can also be obtained from alkenes by an $EtAlCl_2$-catalyzed ene reaction with *p*-toluenesulfinyl chloride (Scheme 53).[147]



**Scheme 53**

Allylic alcohols can be converted to 1,3-dienes by sequential sulfenate–sulfoxide 2,3-sigmatropic rearrangement and *syn* elimination (Scheme 54).[148] The last step used the pyrolytic elimination of sulfoxide, a *cis* elimination discovered by Cram.[149] A paper published by Trost[150] documented this topic in detail.

A useful synthesis of functionalized dienes from alkenes used the initial formation of a stable π-allyl palladium complex, followed by reaction with α-sulfinyl ester enolate and pyrolytic sulfoxide elimination (Scheme 55).[151]

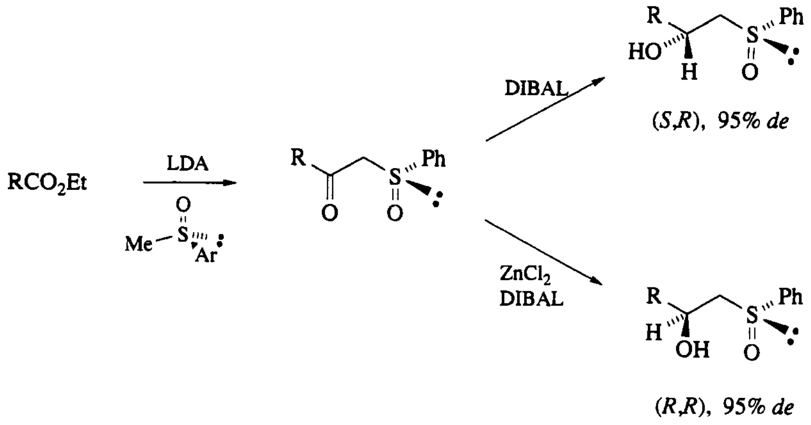
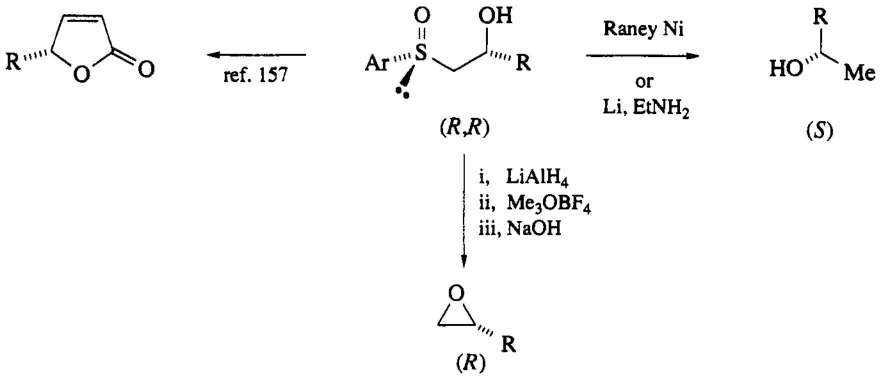
Scheme 57

Optically active β-keto sulfoxides are readily available from esters and methyl *p*-tolyl sulfoxide. The ketone function can be reduced with metal hydrides (DIBAL and $ZnCl_2$/DIBAL) giving, with very high diastereoselectivity, opposite configurations in the resulting β-hydroxy sulfoxides (Scheme 58).[154,155]



Scheme 58

Chiral β-hydroxy sulfoxides are very good intermediates for the synthesis of optically active alcohols,[156] epoxides[155] or butenolides (Scheme 59).[157]



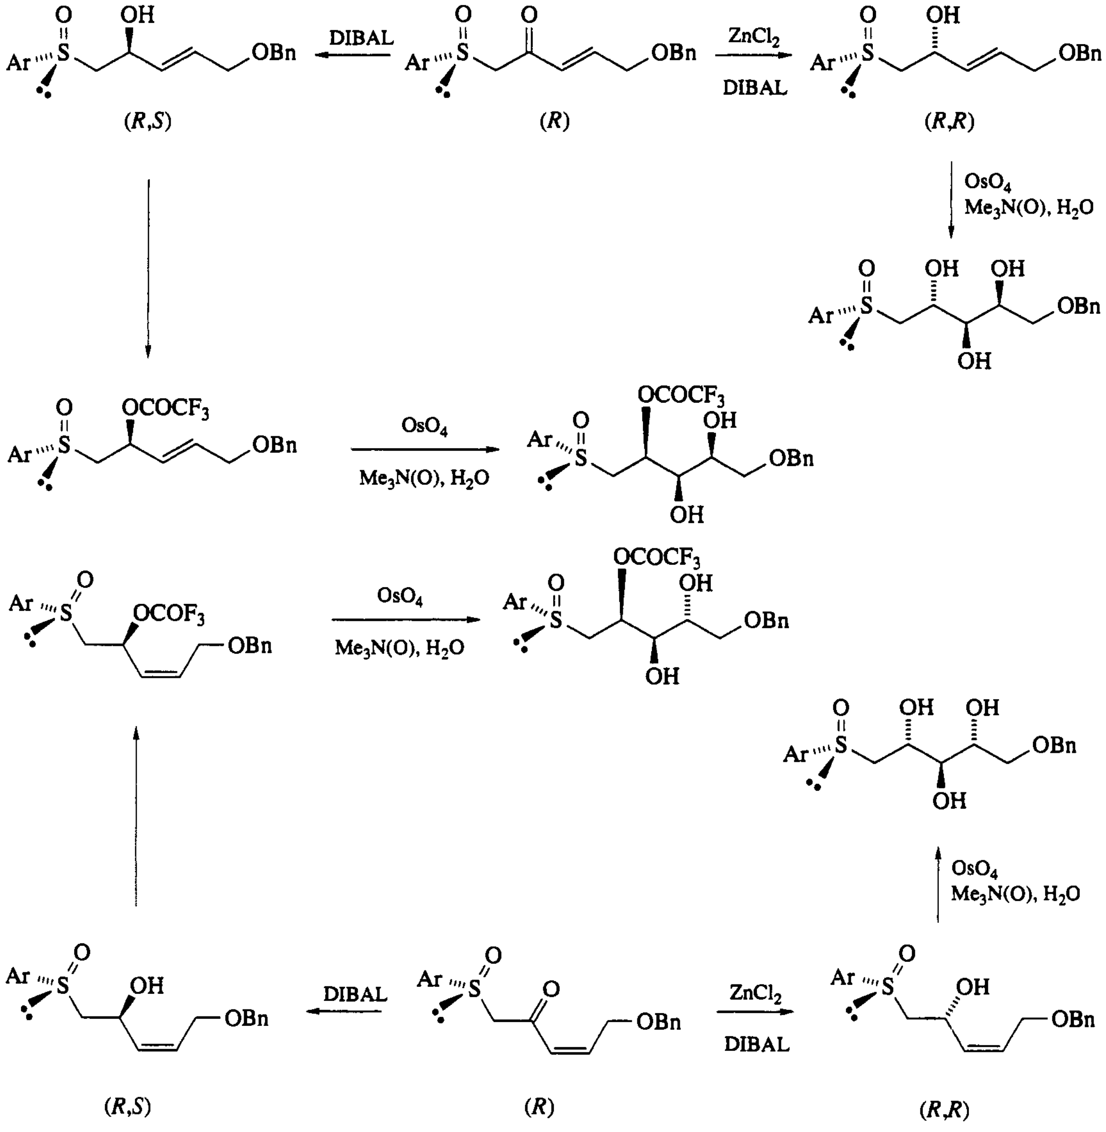
Scheme 59

Allylic and propargylic β-keto sulfoxides could be reduced as well as saturated compounds. Optically active allylic β-hydroxy sulfoxides present some specific interest because of the possible hydroxylation of the double bond leading to vicinal triols. The osmium tetroxide catalyzed hydroxylation reaction of the double bond in the presence of trimethylamine *N*-oxide is highly stereoselective:[158,159] the (*R*,*R*)-β-hydroxy sulfoxide gave only one diastereoisomeric triol as a result of a *cis* hydroxylation of the double bond and a symbiotic effect of the two chiral centers in the asymmetric induction (the (*S*,*R*)-isomer gave a lower *de*).

In the case of the (*S*,*R*)-β-hydroxy sulfoxide, the OH group has to be protected by a trifluoroacetyl group before hydroxylation, which was highly stereoselective and fully controlled by the chiral sulfoxide group.[160] Very similar results were obtained in the case of allylic β-hydroxy sulfoxides having a (*Z*)-geometry on the double bond.[160] Trihydroxy sulfoxides in all possible configurations can therefore be made by this method (Scheme 60).

These trihydroxy sulfoxides are useful molecules in total synthesis because of the possible transformation of the sulfoxide into aldehyde by a Pummerer rearrangement.[159,161] Homoallylic β-hydroxy sulfoxides have also been prepared from β-epoxy sulfoxides, readily obtained from methyl monochloroacetate (Scheme 61a).[162a]

Optically active α-chloro sulfoxides have recently been obtained by a very practical procedure[162b] using NBS and potassium carbonate with the expected inversion of configuration at sulfur. Chloro sulfoxides were shown to be very useful in the synthesis of epoxides[162c] and for α,β-unsaturated ketone homologation (Scheme 61b).[162d]



Scheme 60

## 1.5.4 SULFONES

Although Kohler and Tishler[163] reported the metallation of benzyl sulfones in 1935 and Field[164] later used benzyl sulfones in Grignard reactions, the use of new bases and the easy introduction of a sulfonyl group into a molecule *via* alkyl halides and sodium sulfinate resulted in a major development by Julia[165–170] of the synthetic use of sulfones.

The preparation of 3,7-dimethyl-2-*trans*-4-*trans*-6-*trans*-octatrienoic acid (Scheme 62)[165,166] is a good example of the introduction of a sulfonyl group from sodium sulfinate, of the coupling reaction of a sulfonyl carbanion and allylic bromide and finally of the elimination of the sulfonyl group in basic medium giving the all-*trans* compound. The same method was used for vitamin A synthesis (Scheme 63).[168,170]

In a similar way, Grieco[171] reported the synthesis of *trans*-squalene from *trans*-farnesyl acetate and the corresponding sulfone and Liu[176] prepared difluororetinal analogs.

A modification of vitamin A synthesis was reported recently,[172] using addition of allylic sulfone carbanion to aldehyde followed by a basic double elimination[173] of the resulting β-alkoxy sulfone with excellent stereocontrol (Scheme 64).

Other applications of carbanions α to a sulfone in total syntheses have recently been reported. Most of them used allylic sulfones or allylic halides. Two examples are reported here. In the synthesis of a precursor of cembranolides,[183] a sulfone derived from geranyl bromide was coupled with an allylic alcohol epoxide (Scheme 65). An interesting point was that the coupling reaction gave high yields only when the lithiated sulfone was allowed to react with the epoxymagnesio alkoxide (the lithium salt of the epoxy alcohol did not react at all with the lithiated sulfone).

In the synthesis of an ionophore antibiotic,[184] a bicyclic sulfone made by oxidation of the corresponding sulfide with $PhSeSePh/H_2O_2$ to avoid double bond oxidation was coupled with an allylic bromide in 97% yield and high stereoselectivity. The sulfonyl group was finally eliminated in basic medium to create a *trans*-diene (Scheme 66).

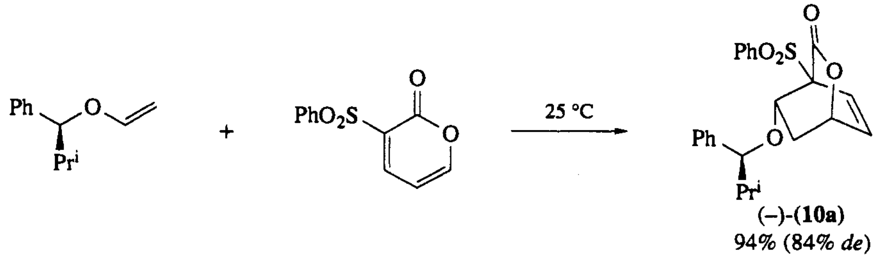
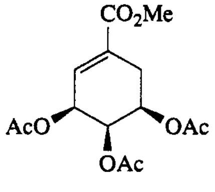
α-Pyrone sulfone[132,178a] is indeed, as we have already shown, very reactive in Diels–Alder reactions. The chiron (–)-(**10a**) was obtained with very high diastereoselectivity from α-pyrone sulfone and optically active vinyl ether (Scheme 69). This lactone was later used[178a] in the asymmetric synthesis of (–)-methyltriacetyl-4-epishikimate (**10b**). β-Sulfonylnitroalkenes were also shown to be reactive alkyne equivalents in Diels–Alder reactions.[178b]

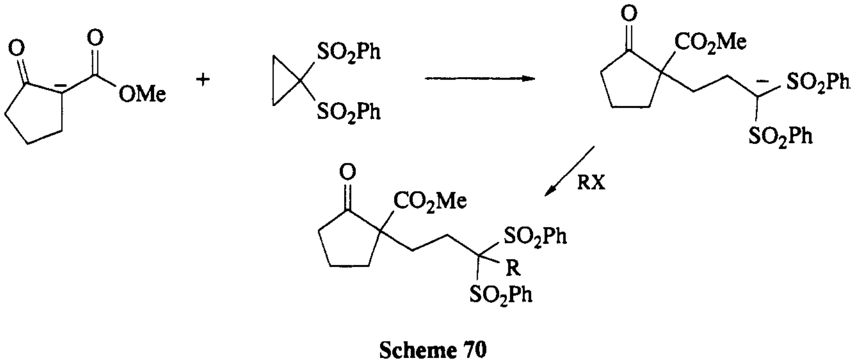


**Scheme 69**



**(10b)**

1,1-Bis(benzenesulfonyl)cyclopropane[179] presents several advantages in organic synthesis: the electron-withdrawing groups on the cyclopropane facilitate its opening by nucleophiles and, since each sulfone can be cleaved to create a carbanionic center, various electrophilic substitutions can be performed. One example is given in Scheme 70.



**Scheme 70**

The Ramberg–Bäcklund reaction is a synthetically useful process in which α-haloalkyl sulfones afford alkenes upon treatment with base.[180] Bromomethanesulfonyl bromide (**11**) is a very useful reagent for such reactions with unusual stereochemical features of the reaction with base.[181,182] Adducts between (**11**) and alkenes are formed in nearly quantitative yield by a light-catalyzed free radical addition. Direct treatment of these adducts with DBN afforded vinylic sulfones, which on treatment with Bu$^t$OK gave a highly stereoselective elimination to the corresponding diene, probably *via* a base-catalyzed isomerization to the corresponding allylic sulfone (Scheme 71).

(*E*)-1,3-butadienyl tosyl sulfone was found to react with dialkylcuprates; the alkyl group was added to the terminal double bond and the newly formed double bond has exclusively (*Z*)-geometry (Scheme 72).[185] It is interesting that starting from butadienyl allyl sulfone, the stereochemistry of the double bonds was maintained during the Ramberg–Bäcklund sulfur extrusion.

In similar work, Julia[186] prepared allyl dienyl sulfones from (*Z*)-2-methyl-1,3-butadienylsulfinate. Addition of various nucleophiles to the diene and Ramberg–Bäcklund reaction then yielded isoprenoid compounds (Scheme 73).

Vinyl sulfones can be easily functionalized in a highly regio- and stereo-selective way: organolithium reagents undergo conjugate addition to afford *trans* adducts in high yield,[189] while organocuprate reagents undergo an amine-directed conjugate addition to afford the *cis* adduct (Scheme 75).[190,191]

**Scheme 75**

The synthesis of the preceding vinyl amino sulfone offers a very good example of a stereospecific sulfide-directed epoxidation (Scheme 76).[192] Oxidation of optically active sulfide alcohol (**12**; readily made from epoxycyclopentadiene[193] and resolved) with MCPBA affords the corresponding sulfoxide, which is in equilibrium with the sulfenate ester. Treatment with pyridine hydrobromide and then phenyl disulfide and bromine gives the bromodiol (**13**), which is simply cyclized to the epoxide with aqueous sodium hydroxide solution (83% overall yield from the sulfoxide). Treatment of the β-epoxy sulfone with DBU followed by *in situ* silylation with *t*-butyldiphenylsilyl chloride affords an 86% yield of vinyl sulfone (**14**). Mesylation of the alcohol moiety followed by immediate treatment with dimethylamine produces the amino vinyl sulfone *via* a *syn* $S_N2'$ substitution.[189]

In a recent total synthesis of (±)-morphine,[194] the key step was a cyclization step induced by intramolecular Michael addition on a vinylic sulfone followed by bromide displacement (Scheme 77). The entire process was highly stereoselective. Methyl-3-phenylsulfonyl orthopropionate was shown to be a good reagent for cyclopentannulation (Scheme 78).[195]

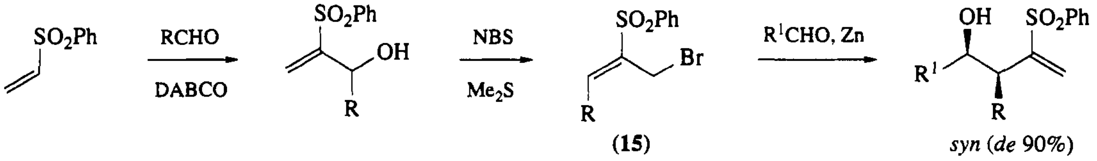
Scheme 79

2-Phenylsulfonic allylic bromide (**15**) reacts with aldehydes in the presence of zinc in high yield and high diastereoselectivity giving *syn*-hydroxy sulfones (Scheme 80).[197,198]

A good example of acyclic diastereoselection was reported by Isobe[199] during 'heteroconjugate addition' on vinylic sulfone. The 'heteroalkene' is indeed a vinylic sulfone with an α-chiral center and a hydroxy group in the allylic or homoallylic position. In the allylic case, a complete *syn* diastereoselection was observed during methyllithium addition. This high stereoselectivity can be explained by the following: the nucleophilic carbanion should coordinate with the oxygen atom by a chelation effect through the

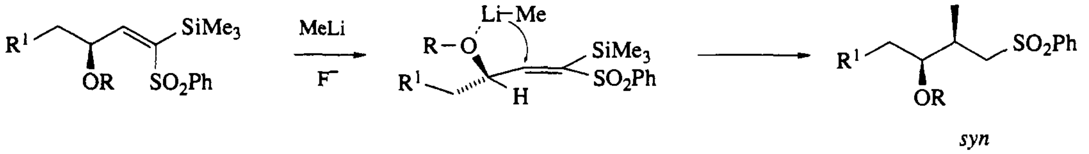


(15)

*syn* (*de* 90%)

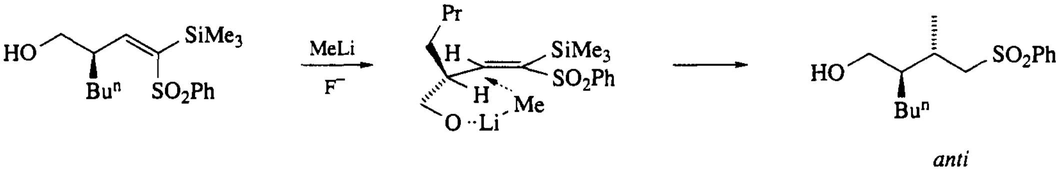
**Scheme 80**

lithium cation so that the nucleophile will have a higher opportunity for attacking the alkene from the oxygen face than from the nonchelating carbon face (Scheme 81).



**Scheme 81**

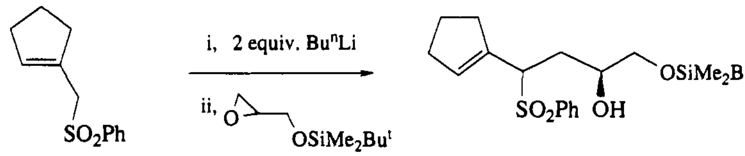
The *anti* diastereoselectivity can be achieved by coordination of the nucleophile to the opposite face of the α-oxygen atom. This was the case with the homoallylic system (Scheme 82).



**Scheme 82**

The heteroalkenes were prepared by Peterson-type alkenation of the corresponding aldehydes with bis(trimethylsilyl)phenylthiomethyllithium [$PhS(Me_3Si)_2CLi$] followed by oxidation to sulfones.

Remarkable diastereocontrol was also reported by Trost[200] during alkylation of allylic sulfones with epoxide. A very high kinetic diastereoselectivity was observed in the case of terminal epoxide and branching on the vinyl carbon proximal to sulfone (Scheme 83).



kinetic control, *de* = 97:3

**Scheme 83**

In the other cases, the diastereoselectivity was higher under thermodynamic control. The remarkable ability to obtain γ-hydroxy sulfones with high diastereoselectivity offers the flexibility to transfer stereocontrol to carbon–carbon bond formation by substitution of the sulfone. This is illustrated by the copper cyanide catalyzed coupling of Grignard reagents (Scheme 84).

Sulfones can also be used in Friedel–Crafts-type cyclizations.[201] One example is shown in Scheme 85, where the cyclization in the presence of aluminum chloride of the allylic sulfone occurred in high yield, showing that sulfones can also become electrophiles. Since a tertiary carbanion has about the same stability as a simple allylic cation, tertiary sulfones can also be cyclized (Scheme 85). These last examples illustrated the 'umpolung' provided by the sulfone since carbanion chemistry was used to introduce the 2-methyl groups.

Sulfonyl group substitutions can also be observed with organoaluminum reagents.[202] They proceed with remarkable ease and good chemo- and regio-selectivity and with a strong bias for formation of an axial C—C bond in cyclohexenyl systems. The unique advantage of the sulfone as a leaving group stems from the ease of alkylation α to the sulfone prior to the substitution. The chemoselectivity of this method was tested by its ability to employ carbonyl adducts. Initial complexation of the free alcohol with

## 1.5.5 CONCLUSION

The variety and number of examples listed in the literature show the efficiency of sulfur-containing molecules in organic synthesis. In the mid-1960s, organic sulfur chemistry was an area for specialists, but currently almost every organic chemist, in some way or another, encounters organosulfur compounds. It was not, of course, possible to review in this chapter all of the literature work in which sulfur-containing groups serve an important auxiliary function in synthetic sequences. It has, however, been attempted to describe most of the reports which have important applications in selective organic synthesis.

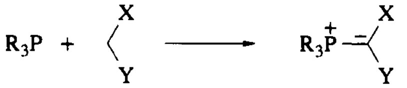
## 1.6.1 ALKYLIDENEPHOSPHORANES

### 1.6.1.1 Synthesis from Tertiary Phosphines and Various Compounds

Tertiary phosphines (especially triphenylphosphine) react with various compounds giving rise to the formation of alkylidenephosphoranes.[1–5] By the addition of carbenes and carbenoids, respectively, to tertiary phosphines especially, alkylidenephosphoranes are available which carry one or two halogen atoms at the α-carbon atom (equation 1).



$$R_3P + :C(X)(Y) \longrightarrow R_3\overset{+}{P}-\overset{-}{C}(X)(Y)$$

(1)

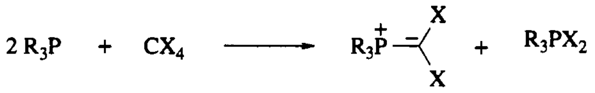
The necessary carbene or carbenoid species are generated from di- or tri-halomethanes with bases (organolithium compounds or alkoxides) or by decomposition of sodium trihaloacetates in the presence of a tertiary phosphine. The resulting haloalkylidenephosphoranes are usually not isolated but react with added carbonyl compounds to give alkenes. The *in situ* formation of dichloromethylenetriphenylphosphorane as well as the analog methylthiochloro compound can be achieved in aqueous sodium hydroxide solution under phase transfer conditions.[6] Bis(phenylthio)- and bis(phenylseleno)-methylenetriphenylphosphorane have also been synthesized by the carbenoid method.[7]

Aliphatic diazo compounds may also be used as a source for carbenes, which combine subsequently with tertiary phosphines to give phosphonium ylides. The reaction requires the presence of $Cu^I$ salts, otherwise phosphazines are formed from the diazo compounds and the phosphines.

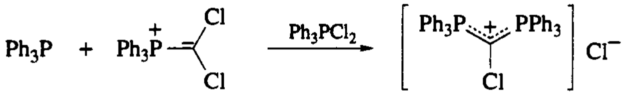
Alkylidenephosphoranes containing the bis(aryl/alkylsulfonyl)methylene functionality may be obtained from aryliodonium ylides and triphenylphosphine, a carbene mechanism presumably being involved.[8]

Ylide formation by capture of electrophilic carbenes with tertiary phosphines has been shown to be a symmetry-breaking allowed pathway.[9] The reverse process, dissociation of a phosphonium ylide into carbene and phosphine,[10] is in agreement with the concept of phosphonium ylides as phosphine–carbene complexes.[11]

Dihalomethylenephosphoranes are easily available from tetrahalomethanes and tertiary phosphines, especially triphenylphosphine (equation 2). From mixed tetrahalomethanes preferably difluoro- and dichloro-methenylenephosphoranes are formed. The primarily resulting dihalomethylenephosphorane may undergo subsequent reaction giving rise to the formation of a semi-ylide salt (equation 3).[12,13]



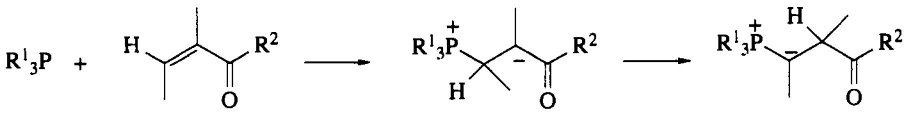
(2)



(3)

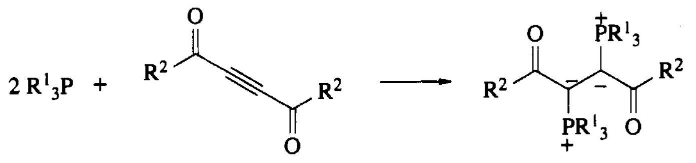
In contrast to triphenylphosphine alkyldi(*t*-butyl)phosphines react with carbon tetrachloride or tetrabromide to give *P*-halo ylides.[14] Usually dihalo ylides are generated *in situ* in the presence of an aldehyde or a ketone whereby the simultaneously formed dihalotriorganophosphorane reacts with a second mole of the carbonyl compound to give dichloroacetals. The addition of zinc dust proved to be favorable in the synthesis of the difluoro-,[15,16] dibromo-,[17,18] and diiodo-methylenetriphenylphosphoranes.[19] Analogous to tetrahalomethanes trihaloacetates react with triphenylphosphine yielding alkoxycarbonylhalomethylenetriphenylphosphoranes.[5] Also 2,2-dichlorohexafluoropropane seems to react with triphenylphosphine by formation of the corresponding ylide.[20]

Phosphonium ylides are also available from the reaction of trivalent phosphorus compounds with activated C—C multiple bonds.[21–23] Phosphines add to the activated C=C double bond of α,β-unsaturated ketones or carboxylic acid derivatives. The zwitterionic intermediate (generally a phosphonioenolate) undergoes 1,2-prototropic shift giving rise to the formation of an alkylidenephosphorane (equation 4). Ylides generated according to this method *in situ* from acrylic acid derivatives[24,25] are difficult to prepare otherwise, because of the easily occurring Hofmann degradation. Several alternative routes for the stabilization of the zwitterionic intermediate leading to other compounds than the desired ylide have been observed.[23]



(4)

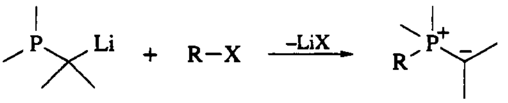
Alkynes having activated C≡C triple bonds react with tertiary phosphines in the molar ratio 1:2 giving rise to the formation of 1,2-bisylides (equation 5).[23] Beyond that some rather complex reactions between phosphines and alkynes are known; however, these are of no preparative importance as unambiguous routes to ylides.



(5)

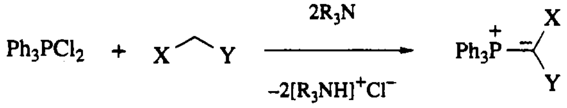
In addition to the synthetic routes described, tertiary phosphines react with miscellaneous compounds (epoxides, nitrilimines, sulfuranes, amidines) leading to phosphonium ylides.[26] These reactions, however, seem not to represent generally applicable methods for the synthesis of phosphonium ylides.

α-Lithiated tertiary phosphines undergo reaction with electrophiles at phosphorus rather than carbon and thus provide a route to a variety of *P*-substituted phosphonium ylides (equation 6).[26–28]



(6)

Dihalotriorganophosphoranes react with activated methylene compounds in the presence of triethylamine yielding stabilized ylides in good yields (equation 7).[29]



(7)

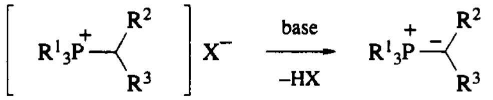
X, Y = CN, $SO_2R$, $CO_2R$, COR, *etc.*

The generation of an ylide from a phosphine oxide and an alkyne is of interest because it represents the reversal of the known intramolecular Wittig reaction of acylated alkylidenephosphoranes.[30]

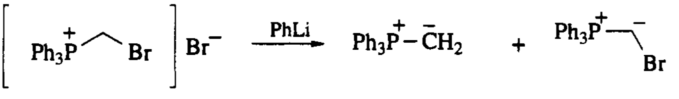
## 1.6.1.2 From Phosphonium Salts

### *1.6.1.2.1 Generation with bases*

The most important method of preparing phosphonium ylides is deprotonation of the corresponding phosphonium salts with suitable bases (equation 8).[31–36] In some instances an alternative ylide may be formed instead of that by deprotonation, if the phosphonium salt is carrying another positively charged substituent in the α-position (*e.g.* equation 9).[35,37–40]

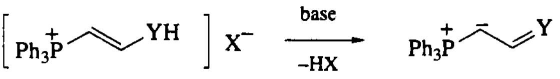


(8)



(9)

An alternative route to ylide synthesis *via* α-deprotonation is the abstraction of a proton from the γ-position of a vinylphosphonium salt (equation 10).[41–43] Complications may arise, however, if the phosphonium salt carries a good leaving group in the β-position so that a vinylphosphonium salt may be formed, or if a β-proton is so acidic that a Hofmann elimination is favored.[35,44–47]



(10)

While triphenylalkylphosphonium salts as ylide precursors unambiguously lead to alkylidenetriphenylphosphoranes, in the case of tetraalkylphosphonium salts ylide formation may take place principally at different α-positions relative to the phosphorus.[48–50] Furthermore an intramolecular transylidation process causes the ligands at the phosphorus in methylenetrialkylphosphoranes to exist alternately as alkyl or as alkylidene substituents, thus giving rise to the formation of isomeric ylides.

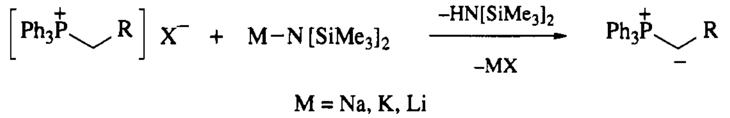
The choice of the appropriate base/solvent system for the ylide generation depends on the acidity of the corresponding salt, the stability of the resulting ylide in the reaction medium and the intended application of the ylide. Thus phosphonium salts with electron-withdrawing groups on the α-carbon, which are capable of stabilizing a negative charge, are deprotonated by relatively weak bases, such as dilute aqueous alkali or ammonia. If there are electron-donating substituents on the α-carbon, stronger bases, such as alkyllithium, are required. Highly reactive phosphonium ylides are usually generated in an aprotic medium and mostly are not isolated but reacted *in situ*.[51]

For many reactions with ylides it is very important to use 'salt-free' solutions. This is especially true for lithium salts because they can affect decisively the course of many ylide reactions, especially the stereochemical course of subsequent Wittig reactions.[52–55]

A great variety of bases has been used to generate ylides from the corresponding phosphonium salts: various nitrogen bases, alkoxides, alkali metal hydrides, carbanionic bases, alkali metal hydroxides and carbonates, ethylene oxides, basic ylides and others.[31,35,36]

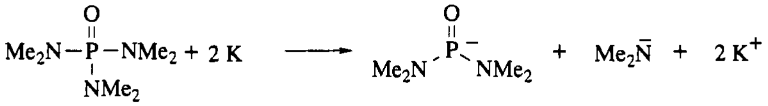
The use of sodium amide proved to be very successful in the synthesis of nonstabilized ylides free from lithium salts.[35,56] The reaction is usually carried out in liquid ammonia, but also a suspension of sodium amide in benzene or THF can be used. Whereas alkyltriarylphosphonium salts are deprotonated in liquid ammonia, in the case of the corresponding tetraalkyl compounds boiling THF is necessary.[48] Mixtures of dry phosphonium salt and powdered sodium amide can be stored indefinitely and hence provide 'instant ylide' mixtures.[57] Upon addition of an ethereal solvent the ylide is quantitatively generated.

Conversion of phosphonium salts to salt-free solutions of ylides can also be effected with sodium bis(trimethylsilyl)amide.[58] As it is soluble in many solvents, and easy to handle and to weigh out, sodium bis(trimethylsilyl)amide is preferred to sodamide in liquid ammonia in many cases (equation 11).[59] The corresponding potassium and lithium compounds can also be used.[60]



(11)

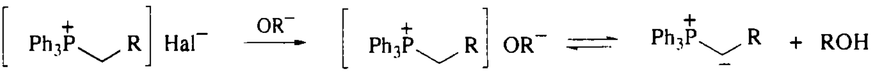
The anions resulting from dissolving potassium in HMPT are also suitable for generating reactive ylides from their corresponding salts, HMPT also turning out to be a favorable solvent for many ylide reactions (equation 12).[61]



(12)

Apart from the bases mentioned a series of other nitrogen bases (ammonia, triethylamine, pyridine, cyclic amidines, lithium diethylamide, lithium diisopropylamide, lithium piperidide, *etc.*) have been used to deprotonate phosphonium salts.

Many alkoxides (especially sodium methoxide, sodium ethoxide, potassium *t*-butoxide and others) can be used as bases in ylide syntheses (equation 13).[35] The reaction is carried out in the corresponding alcohol or another inert solvent. The alkoxide method has some advantages: alkoxide bases are easy to handle, ylide generation may be effected in a homogeneous phase and phosphonium salts carrying corresponding alkoxycarbonyl groups are not cleaved at the alkoxy function. Since, however, ylides may be quenched by the alcohol produced from the base, they are usually generated in the presence (the temperature playing an important factor[38]) of a carbonyl compound to undergo a Wittig reaction. It seems that among alkoxides potassium *t*-butoxide and sodium as well as potassium *t*-pentylate are most suitable for the generation of reactive ylides.[38,62–64] Alkoxide bases are less suitable for the deprotonation of phosphonium salts carrying activated H atoms in the β-position since alkoxides favor cleavage into a phosphine and an alkene.

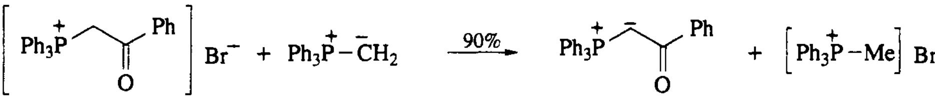


(13)

Very often phosphonium ylides are generated with organolithium compounds (in particular phenyl-, methyl-, *n*-butyl- and *t*-butyl-lithium) as bases.[31,32,34,35] However difficulties may be attached to this method in some cases. When alkyllithium compounds are used, ligand exchange at phosphorus may occur, thus giving rise to the alternative or additional formation of a second ylide. To avoid this phenomenon in the case of triphenylphosphonium salts phenyllithium has to be used as base. Ligand exchange may also be suppressed if one uses, instead of *n*-butyllithium for example, the more bulky tertiary compound.[65] From phosphonium salts carrying halogen at the α-carbon both a proton or a positively charged halogen may be split off and also displacement of an α-halogen by the carbanionic substituent of the lithium compound may occur. β-Substituted phosphonium salts may undergo Hofmann elimination under the influence of organolithium reagents giving rise to the formation of vinyl salts, which subsequently may add a second mole of base at the β-position. Attack of alkyllithium directly at the β-substituent has also been observed.[66] Ylides generated by organolithium compounds may be attacked by excess base yielding metallated ylide species,[39,67] which can act as a more reactive alternative to methylene ylides.[67a,b] Ylides, especially alkylidenetrialkylphosphoranes form complexes with lithium salts,[67f,68] from which the ylide sometimes can be released only at elevated temperatures.

Other carbon bases that have been used successfully to convert phosphonium salts into ylides include sodium methylsulfinate and the corresponding potassium compound[69] (prepared from alkali metal hydride and DMSO), tritylsodium, sodium acetylide and other strongly basic ylides.

Deprotonation of a phosphonium salt by an ylide is a 'transylidation' reaction,[56] which is of importance especially in those cases where ylides are reacted with electrophiles (see Section 1.6.1.3), but may also be applied to isolated phosphonium salts.[35] For an unequivocal reaction the two involved ylides must differ sufficiently with respect to their base strength (as for example in equation 14).

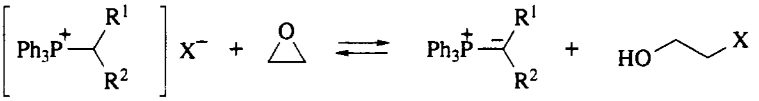


(14)

Aqueous alkali metal hydroxides and carbonates are suitable for the generation of ylides from phosphonium salts, which carry strongly electron-withdrawing groups (*e.g.* acyl, alkoxycarbonyl, cyano, 9-fluorenyl, nitrophenyl and others) at the α-carbon. The resulting stabilized ylides are usually sufficiently stable to be unreactive in water. The above mentioned bases may also be applied to the synthesis of reactive ylides, if the reaction is carried out under phase transfer conditions[46,70–74] in the presence of an aldehyde, which undergoes a Wittig reaction with the *in situ* generated ylide.

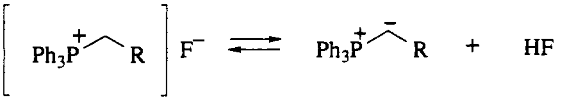
Sodium hydride itself, not only its reaction product with DMSO, is also suitable for deprotonation of phosphonium salts and preference has been given to this base over sodium ethoxide.[75]

Ethylene oxide or 1,2-epoxybutane may also be used for the synthesis of ylides.[76] The resulting ylide is in equilibrium with its conjugated salt (equation 15). The use of ethylene oxide offers some advantages over more conventional bases used in Wittig reactions. The application is simple since ylides and most often also phosphonium salts (from phosphine and alkyl halide) need not to be prepared separately. The reaction medium is neutral, so that base-induced side reactions fail to appear. The method is however less applicable to weakly acid phosphonium salts, since deprotonation requires high temperatures (150 °C).



(15)

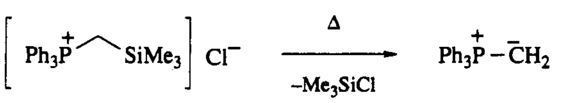
Another ylide synthesis avoiding basic conditions starts from phosphonium fluorides.[77–79] Fluoride ions are basic enough to play the role of the usually added external base, giving rise to the formation of a phosphonium salt/ylide equilibrium (equation 16).



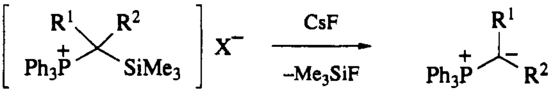
(16)

Ylide generation on alumina or potassium fluoride supported on alumina is of interest since the use of a solvent is unnecessary.[79]

In addition to the generation of phosphonium ylides from phosphonium salts by deprotonation with bases in some instances ylides may result from pyrolysis of phosphonium salts,[80] especially silylated salts (equation 17). Similar fluoride ion induced desilylation (equation 18) of phosphonium salts proved to be a very useful alternative for the synthesis of ylides which are difficult to synthesize by the conventional salt method (as in the case of $R^1$, $R^2$ = alkyl).[81,82] The most effective fluoride source is cesium fluoride and the reaction proceeds at room temperature.



(17)

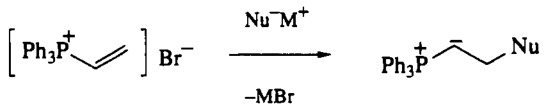


(18)

Phosphonium salts may also be converted to ylides by electrochemical procedures.[80,83] The preparative applicability of these methods, however, seems to be limited.

### *1.6.1.2.2 By addition of nucleophiles to vinyl- and cyclopropyl-triphenylphosphonium salts*

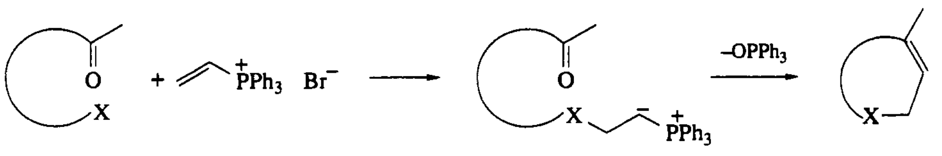
Vinylphosphonium salts are susceptible to nucleophilic attack at the terminal vinyl carbon, thus providing 2-substituted ethylidenephosphoranes (equation 19).[84] This method, developed by Schweizer, has been successfully employed in the addition of a variety of anionic derivatives from alcohols, thiols, amines and others to vinylphosphonium salts, especially to the commercially available vinyltriphenylphosphonium bromide ('Schweizer's reagent').[84–101] The analogous reaction involving alkyl- or aryllithium reagents proceeds in poor yields only, obviously because of ligand exchange processes and a competing elimination reaction transforming the vinyl salt to triphenylphosphine and acetylene. However, when the less basic organolithium cuprates are used as a source of carbanions the desired addition takes place readily.[101] Stabilized carbanions, especially enolate anions, are also well suited as nucleophiles.[92–100]



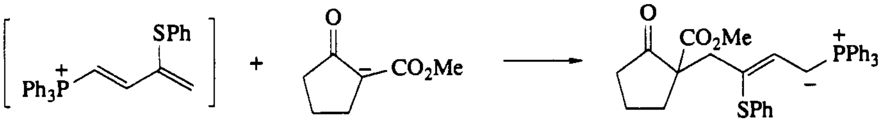
(19)

M = metal; Nu = OR, SR, $NR_2$, $CR_2$, $CR_3$, *etc.*

Ylides generated according to the vinyl salt method are usually not isolated but are quenched *in situ* with a carbonyl compound. Vinylphosphonium salts are most often reacted with nucleophiles containing suitable adjacent carbonyl groups yielding carbonyl substituted ylides, which provides an elegant method for the synthesis of a great variety of cyclic compounds by a subsequent intramolecular Wittig reaction (equation 20). The reaction principle may also be applied to the conjugate addition of a nucleophile to 1,3-butadienyl- and 1,3,5-trienyl-phosphonium salts, leading to the corresponding ylides (*e.g.* equation 21).[84,102,103]

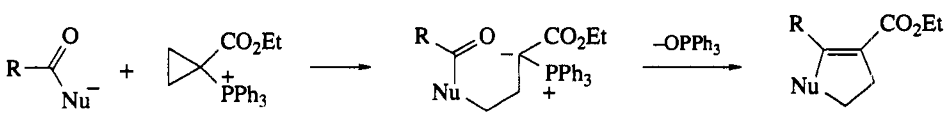


(20)



(21)

Ylides may also be generated by nucleophilic ring opening of cyclopropylphosphonium salts (equation 22).[84,104,105] The resulting ylide undergoes intramolecular Wittig reaction if the attacking nucleophile is carrying a carbonyl group.

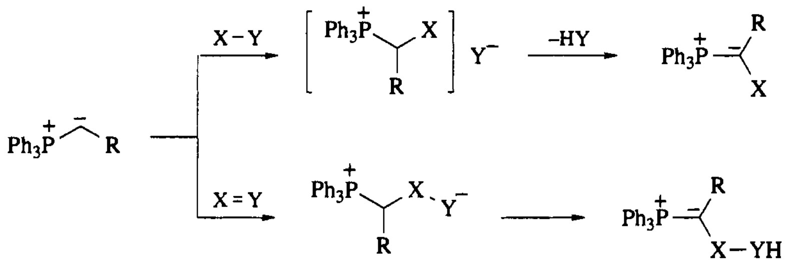


(22)

### 1.6.1.3 From Conversion of Other Phosphonium Ylides

#### *1.6.1.3.1 By substitution of a proton at the ylide carbon atom*

Phosphonium ylides carrying at least one proton at the α-carbon atom react with various electrophilic reagents with formation of α-substituted phosphonium salts or zwitterionic intermediates, from which α-substituted ylides are generated by deprotonation or proton migration, the former reaction being more important (equation 23).[4,106–112]



(23)

If the reaction provides a salt whose acidity is greater than that of the starting phosphorane precursor (for example in the case of X = acyl), a second mole of the starting ylide reacts with the intermediate phosphonium salt in a transylidation reaction[56] (*cf.* equation 14) giving rise to the formation of an α-substituted ylide and the conjugated salt of the original ylide. If the proton of the phosphonium salt generated in the first step is not sufficiently acidic for this proton transfer to occur, the phosphonium salt formed in the first step can be isolated and has to be deprotonated by an external base.

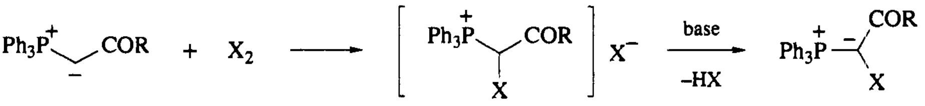
Reactions of ylide anions with electrophiles lead directly to substituted ylides.[109,113]

*(i) Substitution by heterofunctional groups*

α-Heterosubstituents influence the stability of phosphonium ylides markedly since σ-donors and π-acceptor groups, *e.g.* electropositive elements, stabilize ylides, whereas π-donors and σ-acceptors, *e.g.* electronegative elements, destabilize them.[9a]

*(a) Substitution by halogen*

Halogenation of strongly basic ylides with free halogen is accompanied by side reactions and is not suitable for preparative application. Stabilized ylides, *e.g.* acyl- or alkoxycarbonyl-methylenephosphoranes, react with free halogen or various halogen carriers to give halogenated phosphonium salts.[114–118] Subsequent α-halo ylide formation may occur *in situ* by a second mole of the original ylide (transylidation), a base added to the reaction mixture at the beginning, or after isolation of the intermediate salt by an external base (equation 24). Suitable halogen carriers are bromo cyanide (in the presence of triethylamine), dichloro- and difluoro-iodobenzene, chloramine T, iodo bromide and perchloryl fluoride.

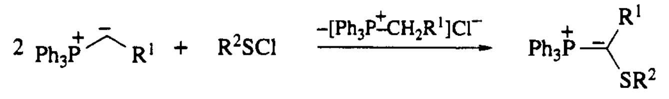


(24)

X = Cl, Br, I; R = alkyl, aryl, *O*-alkyl

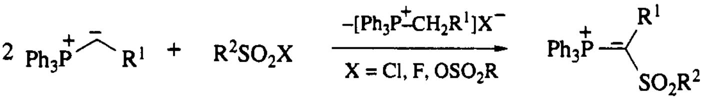
*(b) Substitution by elements of Group 6*

Stabilized, as well as basic ylides, react with sulfenyl chlorides in a transylidation reaction to give alkylthiomethylenephosphoranes (equation 25).[119] In methylenetriphenylphosphorane both α-protons may be substituted by sulfenyl groups. The phenylthio and the methylthio group may also be introduced by *N*-methyl-*N*-phenylthioacetamide and dimethylsuccinimidosulfonium chloride, respectively. These methods avoid the disadvantage of requiring two moles of starting ylide as in the reaction with sulfenyl chlorides.

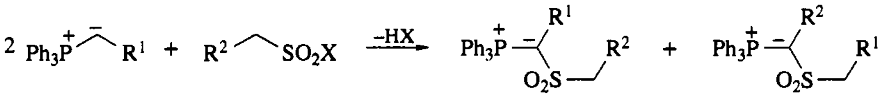


(25)

1-Sulfonylalkylidenephosphoranes are available from simple ylides and sulfonic acid halides or anhydrides in a transylidation reaction (equation 26).[119a] With aromatic sulfonyl chlorides halogenation and sulfenation may occur instead of sulfonation. Aliphatic sulfonyl chlorides give only poor yields of 1-alkanesulfonylalkylidenephosphoranes. Aromatic and aliphatic sulfonyl fluorides are very suitable for the introduction of sulfonyl groups into the α-position of ylides. However, as a consequence of the reaction mechanism (presumably *via* sulfenes) in addition to the expected ylide a rearranged byproduct may be formed (equation 27). 1-Sulfinylalkylidenephosphoranes are synthesized analogously with sulfinyl halides.[119a]

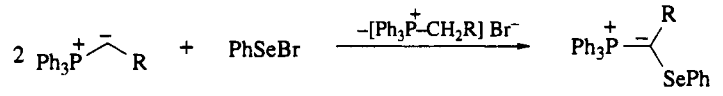


(26)



(27)

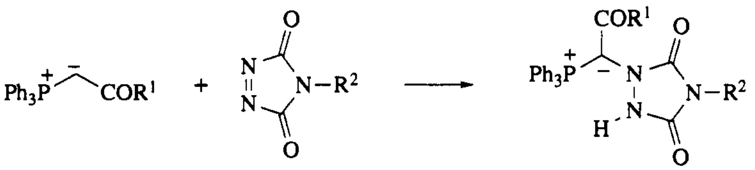
The transylidation reaction of phenylselenyl bromide with two moles of alkylidenetriphenylphosphorane yields 1-phenylselenoalkylidenetriphenylphosphoranes (equation 28).[119]



(28)

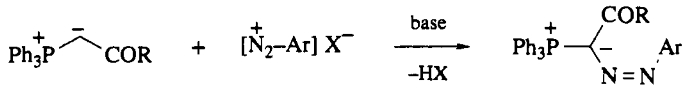
*(c) Substitution by elements of Group 5*

Acyl ylides add to N=N double bonds of azo compounds giving rise to the formation of 1-*N*-substituted alkylidenephosphoranes (*e.g.* equation 29).[120] It should be mentioned that 1-*N*-substituted ylides, which carry only hydrogen or alkyl groups at the nitrogen, are unknown.[10a]



(29)

Coupling of aromatic diazonium salts with stabilized methylenephosphoranes leads to arylazomethylenephosphoranes (equation 30).[121]



(30)

1-Phosphino-substituted ylides are available from simple ylides and chlorodialkyl- or chlorodiarylphosphines (equation 31).[122,123] It depends upon the conditions of the reaction whether the substituted phosphonium salt or the corresponding ylide can be isolated. Methylenetriphenylphosphorane may undergo double phosphinylation. Phosphino-substituted ylides have also been synthesized using 1-alkyl-2-vinylphosphiranes as reagents.[124]

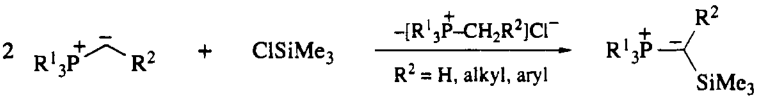
*(d) Substitution by various element–organic substituents*

α-Silylated alkylidenephosphoranes can be synthesized from simple alkylidenephosphoranes and chlorosilanes (especially chlorotrimethylsilane) by transylidation, since the silyl group stabilizes the resulting ylide (equation 37).[81,126,127]



2 R13P R2

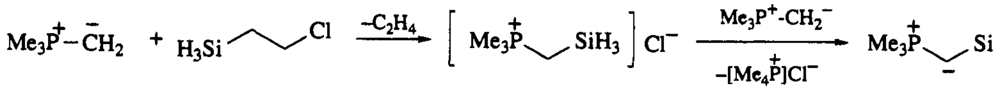
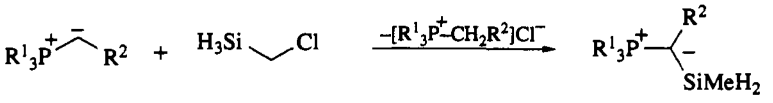
(37)

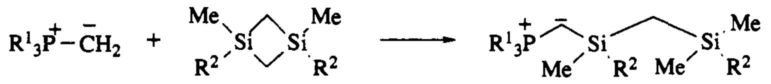
From methylenephosphoranes ($R^2$ = H) both mono- or bis-silylated products may result.[128] Schmidbaur *et al.* have used a variety of compounds for the silylation of ylides.[126] α-Silylated alkylidenephosphoranes are also formed in the reaction of simple ylides with 2-chloroethylsilane (equation 38), chloromethylsilane (equation 39), siletanes, 1,3-disiletanes (equation 40) and the highly strained hexamethylsilirane (equation 41).[129]



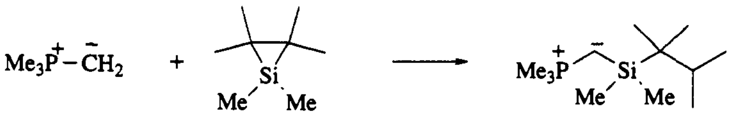
(38)



(39)

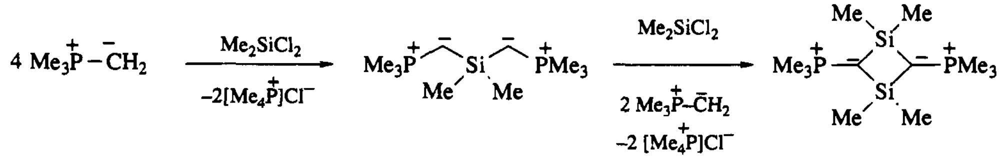


(40)

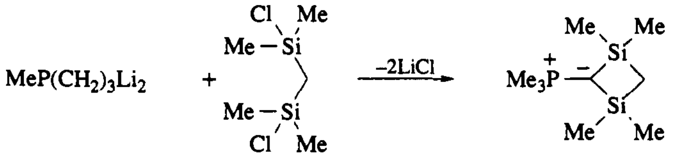


(41)

Reaction of simple ylides with dialkyldihalosilanes leads in a twofold transylidation to the formation of Si-bridged bisphosphoranes (equation 42), which can undergo consecutive reactions with excess starting materials leading to cyclic products. Bis(chlorodimethylsilyl)methane also reacts with dilithiomethylenetrimethylphosphorane to give a methylenephosphorane with an exocyclic ylide function (equation 43).

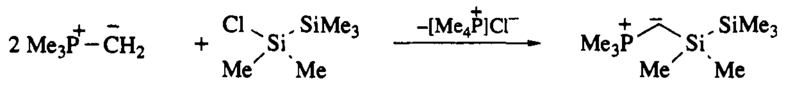


(42)

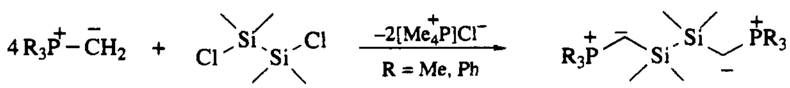


(43)

Analogously to the silyl group the Si—Si unit may be introduced into the α-position of methylenephosphoranes using chlorodisilanes (equations 44 and 45).

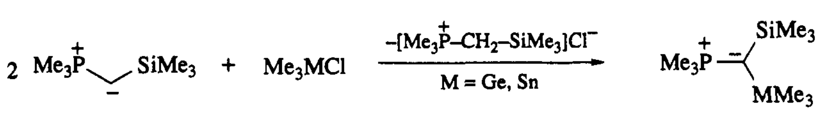


(44)

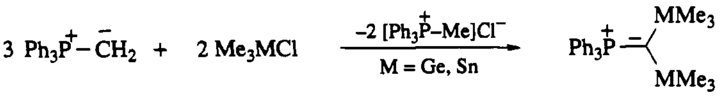


(45)

Germanyl- and stannyl-substituted ylides may be synthesized starting from ylides and germanyl and stannyl chlorides (*e.g.* equation 46).[126] Methylenetriphenylphosphorane is converted into the corresponding disubstituted ylide (equation 47). The monosubstituted derivatives are available by desilylation of 1-trimethylsilylmethylenephosphorane (*cf.* equation 36).

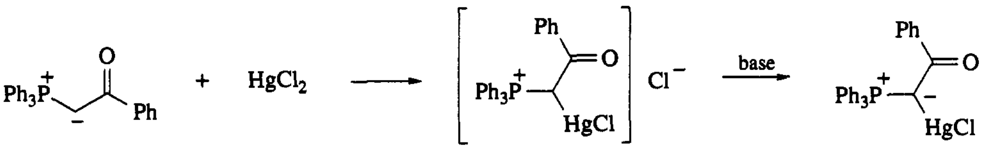


(46)

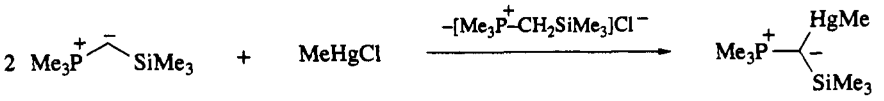


(47)

Stabilized ylides react with mercury(II) chloride giving salts, which can be deprotonated to the corresponding mercury substituted ylides (equation 48).[126] Among reactive ylides only the trimethylsilylmethylenetrimethylphosphorane can be transformed into its mercurated derivative (equation 49).

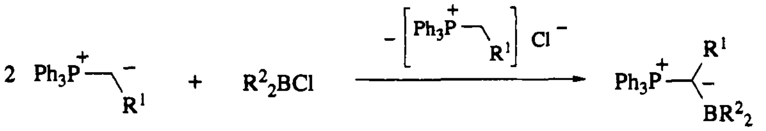


(48)

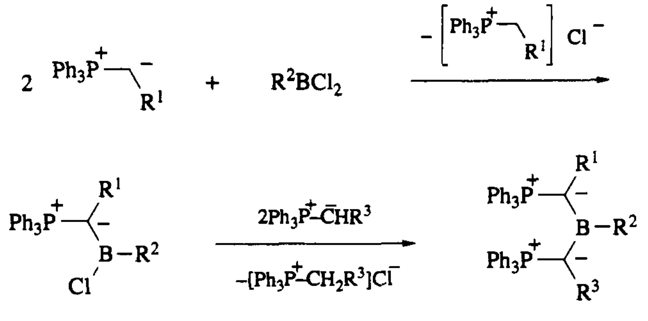


(49)

Dialkylboron-substituted phosphonium ylides have been prepared by reaction of dialkylchloroboranes with alkylidenephosphoranes (equation 50).[130] The reaction of phosphonium ylides with alkyldichloroboranes leads to the formation of boron-bridged 1,3-bisylides (equation 51).[131]



(50)

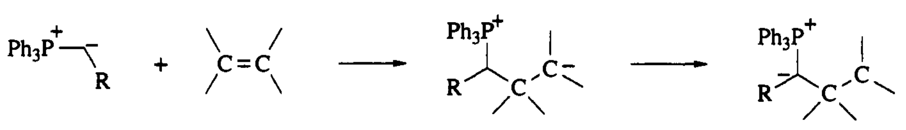


(51)

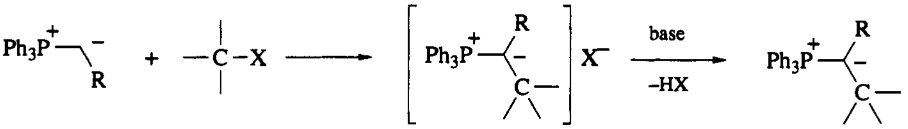
*(ii) Substitution by carbon substituents*

*(a) By alkyl groups*

Substitution of an α-proton in alkylidenephosphoranes by an alkyl group can be achieved by two alternative routes:[106–108,110–112,132] (a) Michael addition to activated C=C double bonds (equation 52); (b) reaction with alkylating reagents to give phosphonium salts, which are subsequently deprotonated by a second mole of the original ylide (transylidation) or an external base (equation 53). Ylide synthesis according to method (a) is restricted to some special cases.[132] Concerning method (b) it should be mentioned that in some instances the second mole of ylide causes β-elimination (Hofmann degradation) instead of α-elimination (transylidation) of the initially formed salt.[110,111,133]

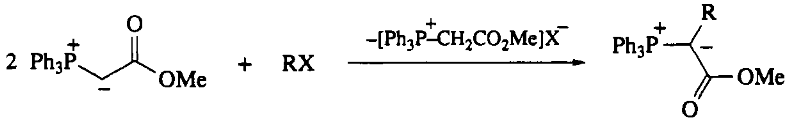


(52)



(53)

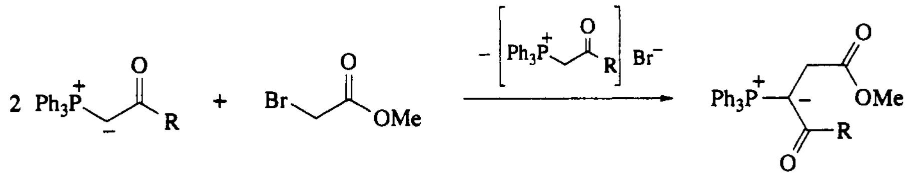
The reaction of ylides with saturated aliphatic alkyl halides (like methyl iodide, ethyl iodide *etc.*) usually stops at the stage of the alkylated salt because the +*I* effect of the aliphatic substituent causes the resulting salt to be a weaker acid than the conjugated salt of the original ylide (which would result in the course of a transylidation reaction).[56,133,134] However since partial transylidation also occurs between alkylidenephosphoranes and phosphonium salts with equal or not very different base and acid strength,[135] mixtures may result from the reaction with saturated aliphatic alkyl halides. At this point it should be mentioned that the synthesis of dialkylated ylides *via* the salt method is also difficult since the preparation of the necessary phosphonium salt is accompanied by β-elimination. The successful synthesis of dialkylated ylides may be achieved by fluoride ion induced desilylation of α-trimethylsilylphosphonium salts (see equation 18). There is no doubt about the course of ylide alkylation in cases where the inductive effect of the new substituent leads to complete transylidation (*e.g.* equation 54).[134]



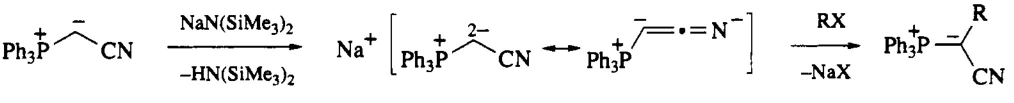
(54)

R = $CH_2CH{=}CH_2$, $CH_2CO_2Me$, $CH_2CN$, $CH_2Ph$, $CH_2CH{=}CHPh$

Ylides with ambident character, like 1-formyl- or 1-acyl-methylenephosphoranes, may be attacked by alkylating reagents (the same is true for acylation) at the α-carbon or at the O atom.[85,136] Bromomethyl acetate *C*-alkylates acylmethylenetriphenylphosphoranes in a transylidation reaction (equation 55).[137] Recently cyanomethylenetriphenylphosphorane has been successfully alkylated *via* its ylide anion, the substituted cyano ylides being accessible more readily in greater variety than previously (equation 56).[113]



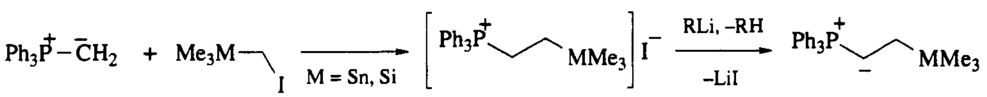
(55)



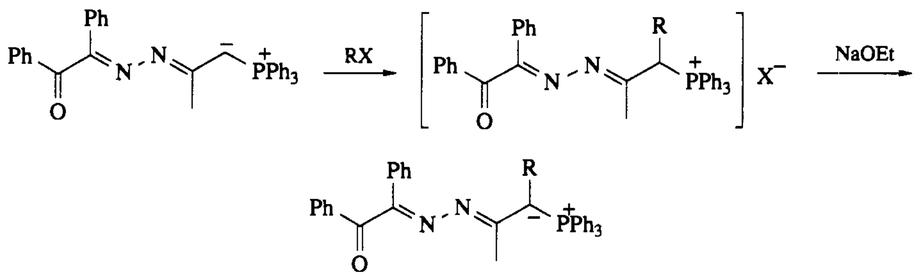
(56)

R = Me, $Bu^n$, $CH_2SiMe_3$, $CH_2Ph$, $CH_2CH{=}CH_2$

Syntheses of complex ylides by alkylation of simple ylides have been achieved in great variety,[110,111,132] using not only alkyl halides (usually containing another functional group) but also other alkylating reagents (Mannich bases,[138] strained cyclic compounds like epoxides,[113b,139] aziridines[140] and siletanes,[141] pyrylium salts[142] and others). Equations (54)–(56), (57),[66] (58),[143] (59),[138] (60)[139a] and (61)[140] give some selected examples.

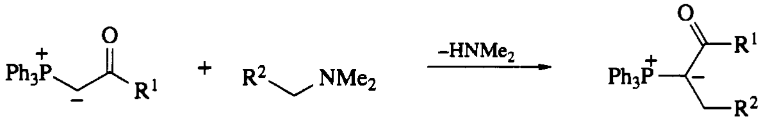


(57)



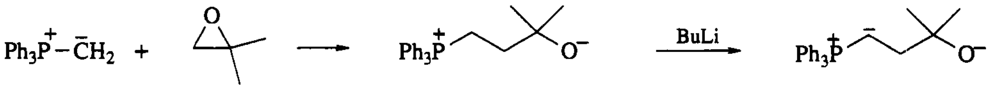
(58)

R = Me, $CH_2CH=CH_2$, $CH_2Ph$

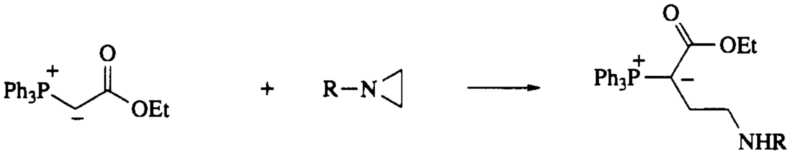


(59)

$R^1$ = OEt, Ph; $R^2$ = Ar, $CH_2CH_2Ar$

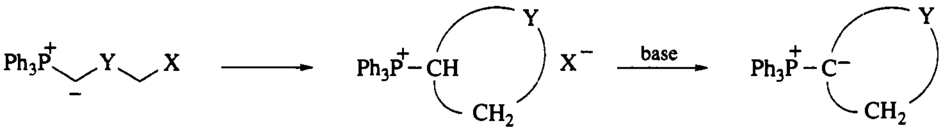


(60)



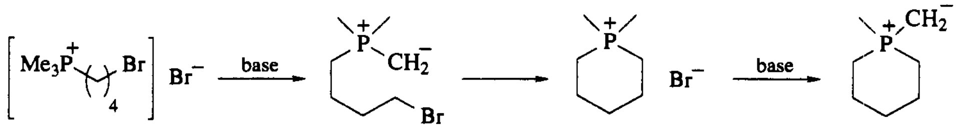
(61)

ω-Haloalkylidenetriphenylphosphoranes undergo intramolecular *C*-alkylation giving rise to the formation of an exocyclic phosphonium salt, which can be deprotonated by a second base (original ylide or an external base) to yield the corresponding exocyclic ylide (equation 62).[144–147]



(62)

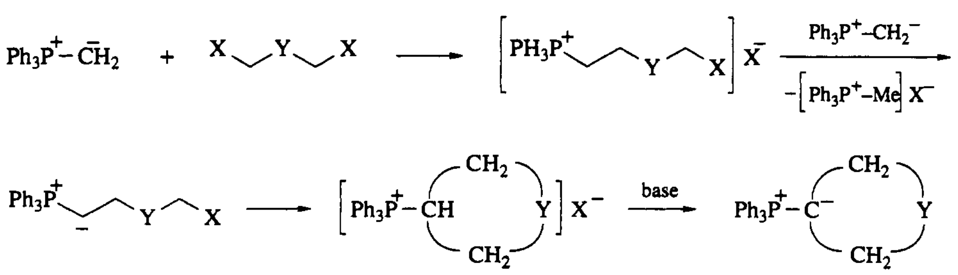
Differing from this course of reaction, in the case of the analogous trialkyl compounds the P atom may be incorporated into the ring system (equation 63).[148]



(63)

For a successful intramolecular *C*-alkylation of alkylidenetriphenylphosphoranes it is required that the conjugated salt of the starting ylide can be synthesized from triphenylphosphine and a 1,ω-dihalide. As a consequence of this fact intramolecular *C*-alkylation often fails in the aliphatic series with Y = $(CH_2)_n$, with the exception of $n$ = 1, 2. This difficulty can be overcome by the combination of the inter- and intramolecular *C*-alkylation of ylides (equation 64).[144–146]

Two moles of methylenetriphenylphosphorane are reacted with one mole of a dihalogen compound. In the first step methylenetriphenylphosphorane is *C*-alkylated yielding an ω-halophosphonium salt, which subsequently reacts with a second mole of methylenetriphenylphosphorane forming a transylidation equilibrium with methyltriphenylphosphonium halide and an ω-halogenated ylide. This compound undergoes intramolecular *C*-alkylation, in the course of which the resulting exocyclic phosphonium salt



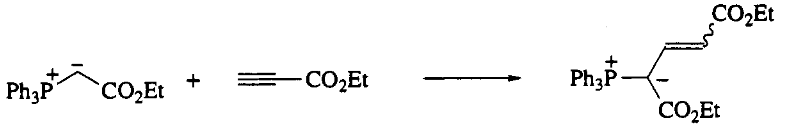
(64)

is formed and precipitates together with the methyltriphenylphosphonium halide (from the transylidation step) from the benzene solution. As a consequence of the precipitation the transylidation equilibrium is permanently disturbed so that the reaction takes place with complete formation of both phosphonium salts. These can be separated by recrystallization from water. From the resulting cycloalkyltriphenylphosphonium salt the corresponding cycloalkylidenetriphenylphosphorane may be generated with a base. Deprotonation may sometimes occur immediately under the influence of a third mole of methylenetriphenylphosphorane. Usually the exocylic alkylidenetriphenylphosphoranes synthesized are not isolated but reacted *in situ*, mostly in a Wittig reaction.

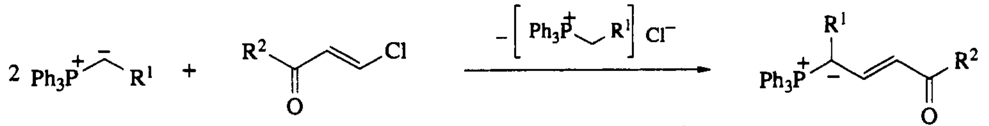
The efficiency of this method is impressively proved by the synthesis of the skeleton of shikimic and chinic acid starting from an open chain sugar derivative and the synthesis of optically active cyclopentanediol synthetic building blocks from tartaric acid.[149]

### *(b) By alkenyl and alkynyl groups*

The alkenylation of alkylidenephosphoranes may be achieved, by analogy to the alkylation, either by Michael addition to conjugated alkynes and allenes or by reaction with alkenylating reagents.[110,111,132b,150,151] Michael addition is restricted to stabilized ylides (*e.g.* equation 65); however, in one case the resulting product has been observed to fragment in a retro-Michael reaction.[152] More reactive alkylidenephosphoranes and alkynes give rise to the formation of four-membered adducts, which undergo ring opening to yield alkenyl-substituted ylides in which the original P—C function has been cleaved.[150] 4-Oxo-2-alkenylidenetriphenylphosphoranes can be prepared from reactive or stabilized ylides and 2-chlorovinyl ketones in a transylidation reaction (equation 66).[150a]



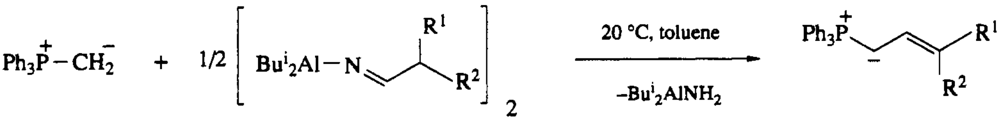
(65)



(66)

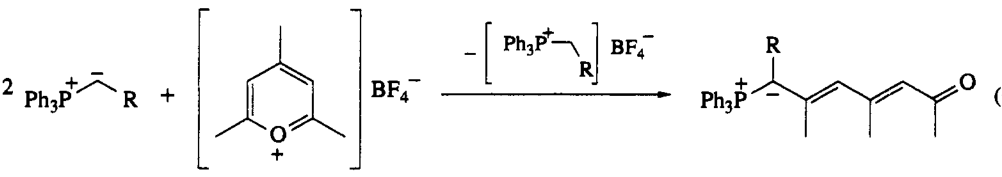
$R^1$ = $CO_2Et$, COMe, SPh, Ph, $CH_2Ph$, CH=CHMe; $R^2$ = alkyl, phenyl

Methylenetriphenylphosphorane reacts with alkylideneaminodialkylaluminum compounds (available from diisobutylaluminum hydride and nitriles) to give allylidenetriphenylphosphoranes (equation 67). In the case of $R^1$ = *n*-alkyl, $R^2$ = H, predominantly (*Z*)-allylidenephosphoranes are formed; branching of $R^1$ leads to an increasing portion of (*E*)-isomer. The method has also been applied to the synthesis of cyclic and acyclic bisallylidenephosphoranes.[153]



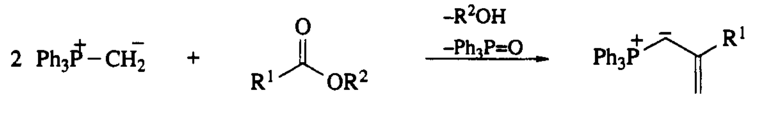
(67)

2,4-Alkadienylidenephosphorane can be synthesized from simple ylides and pyrylium or pyridinium salts (*e.g.* equation 68).[150a] The resulting ylides may undergo spontanous intramolecular Wittig reaction.



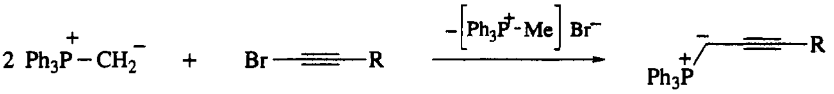
(68)

Esters of aromatic acids react with an excess of methylenetriphenylphosphorane giving rise to the formation of allylidenephosphoranes (equation 69).[150a]



(69)

Alkynyl substituted alkylidenetriphenylphosphoranes are available from the transylidation reaction of methylenetriphenylphosphorane with bromoalkynes (equation 70) or alternatively with 1,1-dibromoalkenes in the presence of a third mole of original ylide.[154]

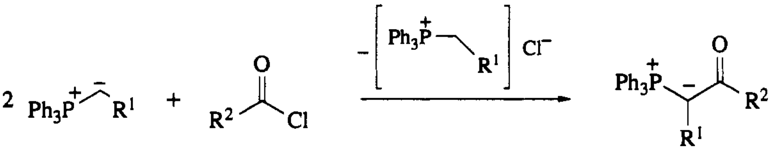


(70)

### *(c) By acyl groups and their derivatives*

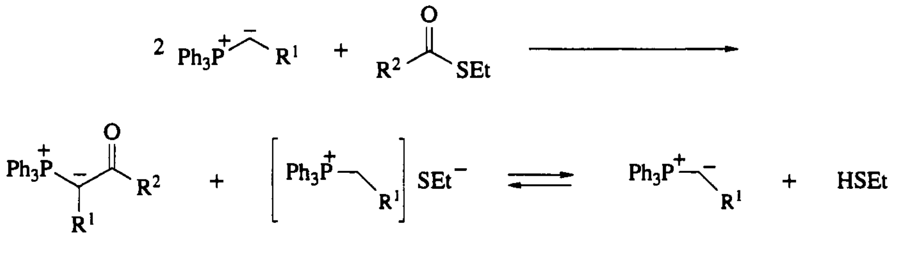
Acyl halides, activated esters, carboxylic anhydrides and *N*-acylimidazoles react with alkylidenephosphoranes to yield acylated ylides.[106,110,111,155-157]

Acid chlorides react readily with alkylidenephosphoranes. Owing to the strongly electron-withdrawing effect of the acyl group, the initially formed salt is a sufficiently strong acid to undergo transylidation very easily with a second mole of starting ylide (equation 71). The method has been applied to reactive[158-160] as well as to resonance-stabilized (especially ester-stabilized) ylides,[121d,143,161-164] β-ketoalkylidenephosphoranes however usually yield *O*-acylated products. The second mole of starting ylide necessary for a transylidation may be substituted by triethylamine if the amine is a stronger base than the ylide, as is usual in the case of stabilized phosphoranes.[156,165] Under the influence of the added amine or the original ylide hydrogen chloride may be eliminated from acid chorides containing activated α-hydrogen. The ketenes so formed may react with ylides to give allenes.[166] Acid fluorides have also been used for the acylation of ylides.[167]



(71)

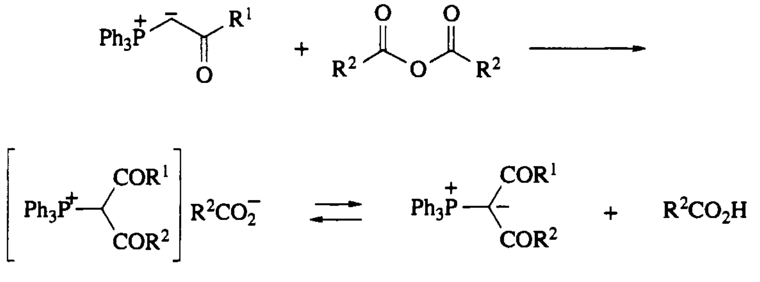
A disadvantage of the acylation method with acid halides is the requirement of two moles of starting ylide, one acting as a base to deprotonate the initially formed acylated phosphonium salt (although the precipitating salt may be used for the regeneration of the starting ylide). This disadvantage can be removed by the use of thiocarboxylic acid *S*-ethyl esters as acylating reagents (equation 72).[156] The phos-



(72)

phonium thiolate initially formed by transylidation eliminates mercaptan thus generating the second mole of starting ylide and removing it from the equilibrium by reaction with further thioester. This method usually supplies purer products and better yields than the acid chloride acylation.

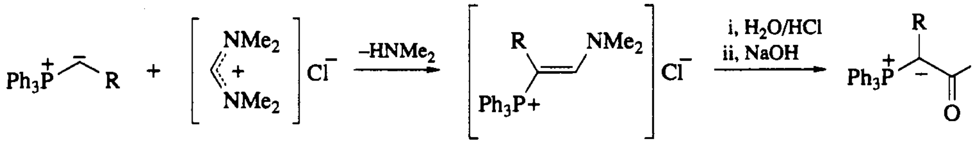
In general, salt-free solutions of ylides do not react with methyl or ethyl esters of carboxylic acids. Better results can be obtained when activated esters (*e.g.* phenyl or pyridyl esters) are used for acylation.[121d,166c] Acylation with carboxylic acid anhydrides also requires only one mole of starting ylide (equation 73).[156,163]



(73)

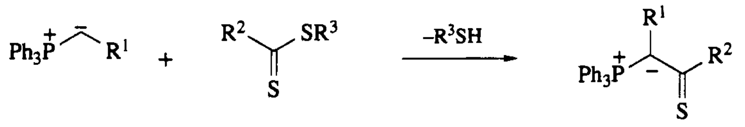
This route proved to be advantageous in the case of resonance-stabilized ylides since there are no problems in separating the acylated ylide from a phosphonium salt resulting from transylidation, and *O*-acylation does not occur when β-keto ylides are used as starting materials. The acylated ylide is generated from the initially formed phosphonium carboxylate by heating or with an alkali metal hydroxide. Cyclic anhydrides, like succinic or glutaric anhydrides, may also be used as acylating reagents which give rise to the introduction of an ω-carboxy substituted acyl group.[168]

Formylation of alkylidenetriphenylphosphoranes has been achieved with formic esters, *N*-formylimidazole, formyl acetate, chloromethylenedimethylammonium chloride and tetramethylformamidinium chloride. The formamidinium compound leads primarily to vinylphosphonium salts which can be easily hydrolyzed without isolation thus providing a very efficient route to formylalkylidenephosphoranes (equation 74).[169] The preparation of α-formyl substituted ylides with formic ester could be improved by adding tertiary butoxide to the starting ylide before admixture of ethyl formate as formylating reagent, thereby circumventing the necessity for transylidation and increasing the yield drastically.[170]



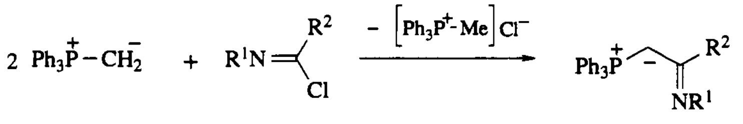
(74)

The introduction of the thioacyl group may be achieved by analogy to the acylation using dithiocarboxylic acid esters (equation 75), however side reactions may occur.[171]



(75)

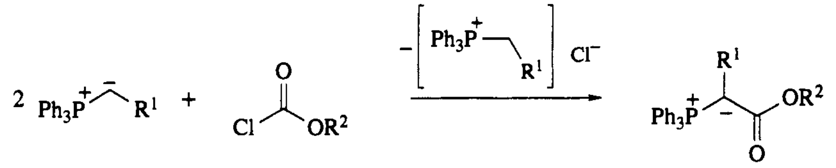
2-Iminoalkylidenetriphenylphosphoranes result from the transylidation reaction of methylenetriphenylphosphorane with imidoyl chlorides (equation 76),[172a] or from Michael addition of ylides to the C═C bond of ketenimines[172b] (formed from carbodiimide and ylides in the initial step).



(76)

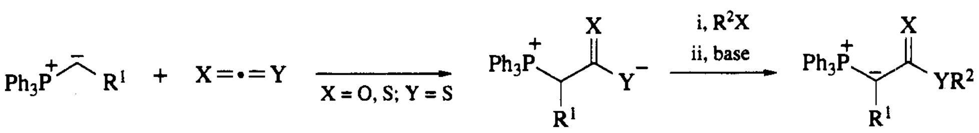
*(d) By derivatives of the carboxy group*

Ylides carrying α-substituents derived from the carboxy group (alkoxycarbonyl, alkylthiocarbonyl, alkylthiothiocarbonyl, cyano) have been synthesized by different routes.[173,174] Ester-substituted ylides are prepared from simple ylides and alkyl chloroformates in a transylidation reaction (equation 77). Using two moles of potassium bis(trimethylsilyl)amide (one for the generation of the starting ylide from its salt, the other for the deprotonation of the substituted salt) permits efficient carbalkoxylation with only one equivalent of valuable starting ylide.[175]



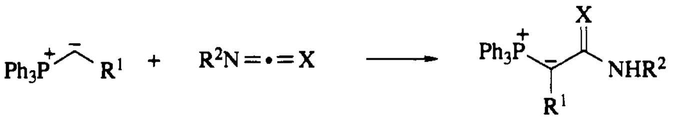
(77)

The synthesis of ylides which are α-substitued with a derivative of the carboxy group can also be achieved *via* the addition of simple ylides to heteroallenes. The reaction with carbon oxysulfide gives rise to the formation of betaines from which alkylthiocarbonylalkylidenephosphoranes may be generated by alkylation and subsequent deprotonation (equation 78; X = O, Y = S).[176] Carbon disulfide reacts in a similar way yielding (alkylthio)thiocarbonyl-substituted ylides (equation 78; X = S, Y = S).[177] These compounds are also available from the reaction of simple ylides with trithiocarbonates or dithiochlorocarbonates in analogy to the acylation of ylides (see equations 71 and 72).[173]



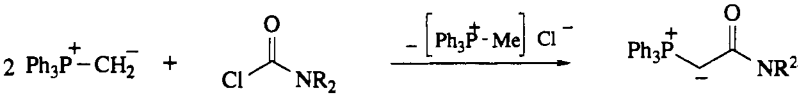
(78)

Alkylidenephosphoranes which carry a carbamoyl or thiocarbamoyl group in the α-position are formed from ylides and isocyanates or thioisocyanates (equation 79).[164,173] If the starting ylide has no activated α-H atom the reaction with thioisocyanates stops at the betaine intermediate (see equation 78) which can subsequently be alkylated and transformed into the corresponding substituted ylide with an external base.



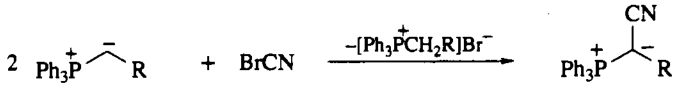
(79)

Carbamoylmethylenephosphoranes can also be synthesized from methylenetriphenylphosphorane and carbamoyl chlorides in a transylidation reaction (equation 80).[158]

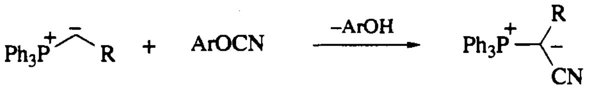


(80)

The cyano group may be introduced into the α-position of ylides by bromocyanide (equation 81) or with cyanic acid aryl esters (equation 82).[173,174]



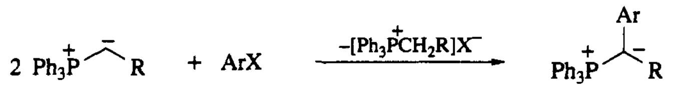
(81)



(82)

### (*e*) *By aryl and heteroaryl groups*

The substitution of a H atom at the α-C atom by an aryl group may be achieved with chloropolynitrobenzenes or hexafluorobenzene, whereby transylidation takes place (equation 83).[178,167] A variety of heteroaryl groups can be introduced in an analogous manner.

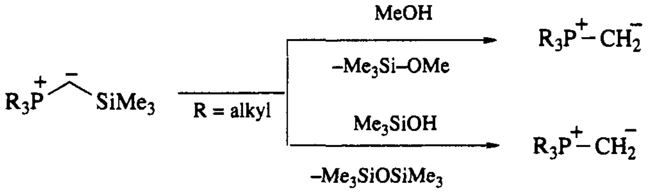


(83)

### *1.6.1.3.2 By substitution of a heterosubstituent at the ylide carbon atom*

Besides protons a series of heteroligands in the α-position of phosphonium ylides can also be substituted, giving rise to the formation of new alkylidenephosphoranes.[179] Halogen atoms have been substituted by carbon groups (with lithium organyls or acyl chlorides) or another halogen. Reaction of α-lithiated ylides (see equation 35) or ylide anions[113] with electrophiles may be considered as substitution of an alkali metal substituent at the ylide carbon atom.

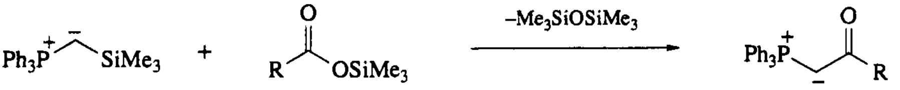
Most important is the substitution of the trimethylsilyl group.[179,180] In this way phosphonium ylides have been generated which could not, or only with difficulties, be synthesized by other methods. Desilylation may be achieved using methanol or trimethylsilanol (substitution of trimethylsilyl by hydrogen), heterosiloxanes (substitution of trimethylsilyl by element–organic groups), acid chlorides, thioesters, anhydrides and trimethylsilyl esters (acylation),[149b,181] and halogenosilanes (transsilylation). Equations (84)–(87) give some examples.



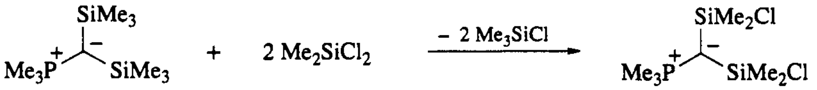
(84)

(85)

$n = 2$, M = As; $n = 3$, M = Ge, Sn, Pb



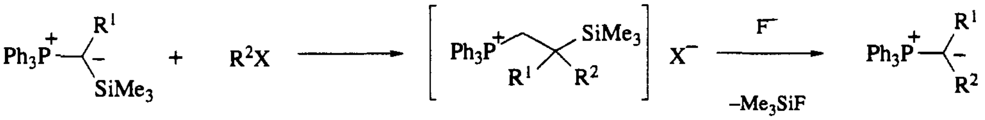
(86)



(87)

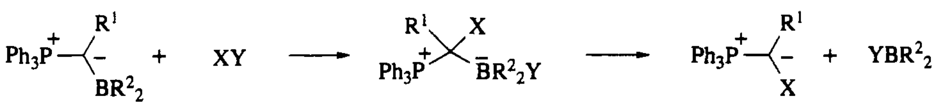
Ylides add to heteroallenes (see equations 78 and 79). In the case of silyl-substituted ylides the initially formed betaine stabilizes by silyl group migration instead of proton migration.[179]

α-Trimethylsilylalkylidenephosphoranes can be transformed into α-trimethylsilylphosphonium salts which can be desilylated by fluoride ions, thus providing a method of substituting trimethylsilyl by alkyl[81] or iodine[182] (equation 88, see also equation 18)



(88)

Dialkylborylalkylidenetriphenylphosphoranes react with polar or polarizable compounds *via* onium complexes to give new ylides, in which the dialkylboryl group has been substituted, and the corresponding organoboron compounds (equation 89).[183]



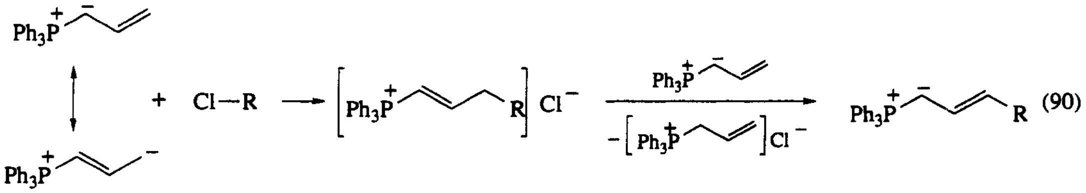
(89)

XY = $Br_2$, DOMe

### *1.6.1.3.3 From reactions which do not take place at the ylide carbon atom*

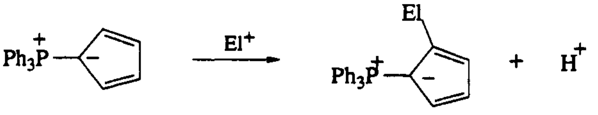
Many alkylidenephosphoranes can be transformed into new phosphonium ylides by reactions which take place in the side chain of a parent ylide, the α-C atom of the ylide group not being involved.[184]

Allylidenetriphenylphosphoranes react with a series of chloro compounds (alkyl chloroformates, acyl chlorides, 3-chloroacrylates, 2-chlorovinyl ketones, phosphorus chlorides) and other electrophilic compounds at the γ-C atom.[184–188] Abstraction of a proton from the γ-position of the resulting phosphonium salts by a second mole of starting ylide (or proton migration) gives rise to the formation of γ-substituted derivatives of the original allylidenephosphoranes (equation 90).



(90)

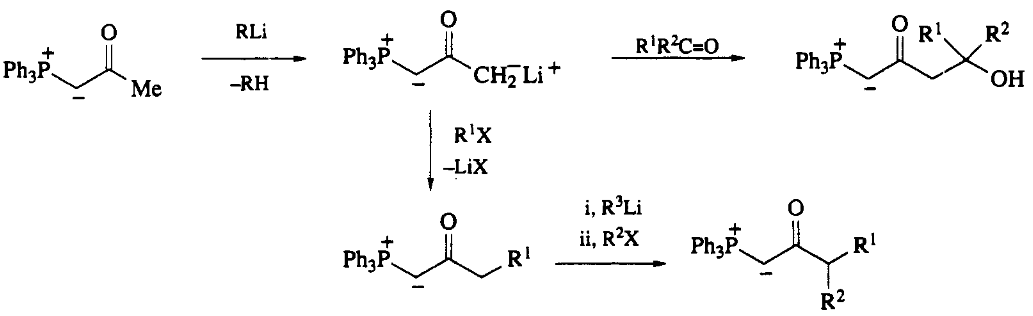
The extremely stable cyclopentadienylidenetriphenylphosphorane and its derivatives are too inactive to undergo typical ylide reactions. The cyclopentadienyl ring, however, may be substituted by a variety of electrophiles in the 2-position (equation 91).[184]



(91)

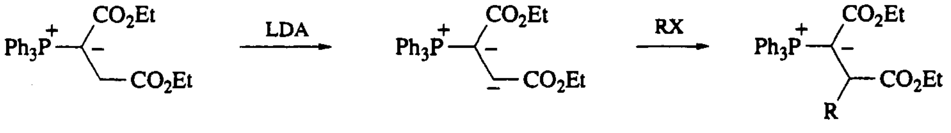
El = alkyl, acyl, azo, nitro *etc.*

Treatment of acetylmethylenetriphenylphosphorane with *n*-butyllithium or lithium diisopropylamide results in abstraction of a methyl proton to form an ylide anion. Reactions of the 1,3-dicarbanion with electrophilic compounds including alkyl halides, aldehydes, ketones and benzoate esters occurs at the terminal carbanion site to afford a variety of substituted β-ketophosphonium ylides (equation 92).[184,189,190]



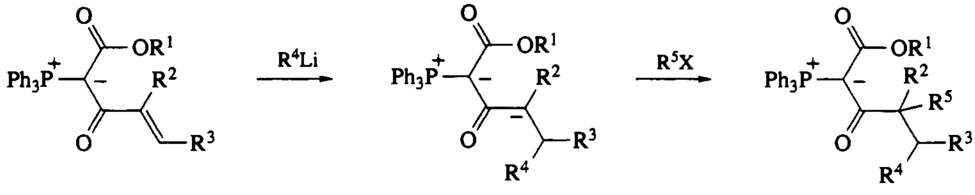
(92)

Converting the resulting monosubstituted ylide into the corresponding secondary ylide anion followed by another alkylation may give rise to the formation of disubstituted 2-oxoalkylidenephosphoranes. The diacetylmethylenetriphenylphosphorane can be deprotonated selectively at one or both methyl groups. Subsequent treatment with an alkyl halide leads to the corresponding mono- or di-alkylated ylide. Ylide anion formation followed by alkylation could also be achieved with the ylide which is readily available from the addition of triphenylphosphine to diethyl fumarate (equation 93).[191]



(93)

Another route to substituted ylides *via* ylide anions involves charge-directed addition of a wide range of carbon nucleophiles to γ,δ-unsaturated acylphosphoranes yielding intermediate anions which further react with electrophiles, mostly alkyl halides (equation 94).[161,184,192]

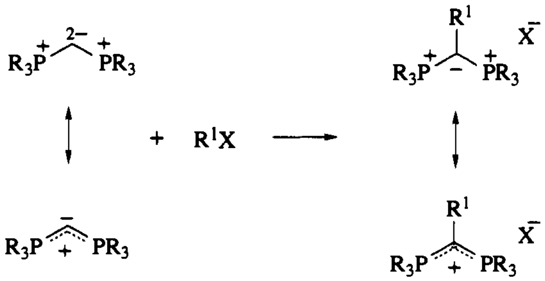


(94)

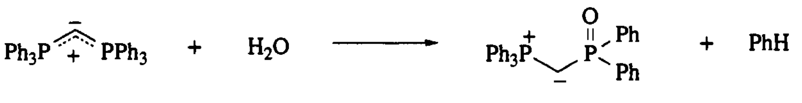
Generally alkylidenephosphoranes that carry in addition to the ylidic function another reactive site (*e.g.* a second ylide function, an additional phosphonate group, a halogen or a silyl substituent) may react at this additional functional group thus providing a derivative of the original ylide.[184,193–195]

### *1.6.1.3.4 From carbodiphosphoranes*

Carbodiphosphoranes (*cf.* Section 1.6.2.1) react with a series of halogen compounds including bromine, hydrogen chloride, alkyl halides, acyl chlorides, sulfenyl chlorides, diorganohalogenophosphines and silyl chlorides, giving rise to the formation of semi-ylide salts which formally contain an ylidic function, being however best described as salts of diphosphaallyl cations (equation 95).[196–201] Phenylcarbodiphosphoranes are converted by water into stable 1-phosphinylmethylenephosphoranes (equation 96).[196–198]

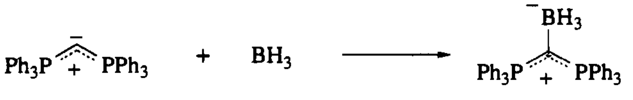


(95)



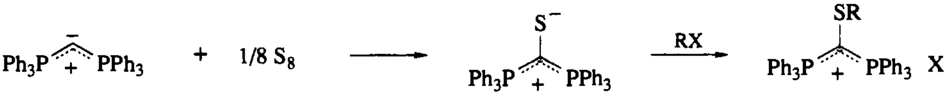
(96)

Borane yields zwitterionic compounds with partial ylide structure (equation 97).[199,201]



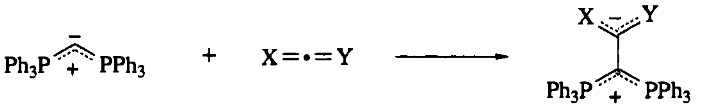
(97)

The reactions with sulfur or selenium result in the formation of betaines, which can be alkylated to give semi-ylide salts (equation 98).[202] The reactions of hexaphenylcarbodiphosphorane with a series of heteroallenes also lead to betaines which on thermolysis yield new cumulated ylides (equation 99, *cf.* equation 120).

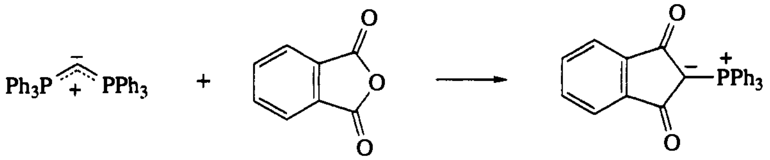


(98)

The bridging oxygen in aromatic carboxylic anhydrides may be exchanged by the ylide function in the reaction with hexaphenylcarbodiphosphorane (*e.g.* equation 100).[203]



(99)



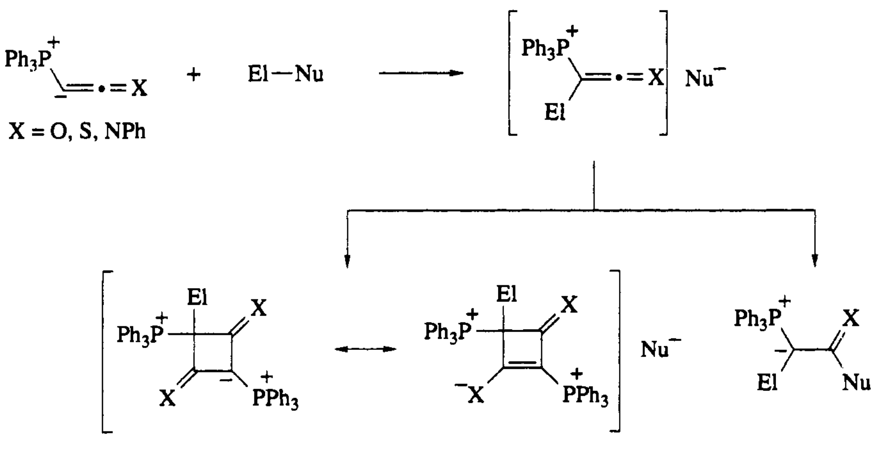
(100)

### 1.6.1.3.5 *From vinylidenephosphoranes*

'Simple' alkylidenephosphoranes can be synthesized from vinylidenephosphoranes by various routes.[204,205]

*(i) By nucleophilic substitution*

Addition of an electrophile to the lone pair of oxo-, thioxo- and imino-vinylidenephosphoranes transforms the nucleophilic $\pi^4$–$\pi^4$ system into the dipolar $\pi^4$–$\pi^2$ system of a ketene. The resulting phosphonium salt becomes a true dipolar ketene which, as such, reacts in a known manner (equation 101). Whenever the anion Nu⁻ is a stronger nucleophile than the original cumulated ylide, the new alkylidenephosphorane will be formed, in which compound ElNu has added to the parent vinylidenephosphorane. If the starting phosphacumulene ylide is a stronger nucleophile than Nu⁻, the intermediate salt always reacts with a second molecule of unreacted ylide in a [2 + 2] cycloaddition to give 1,3-cyclobutanedione derivatives.



(101)

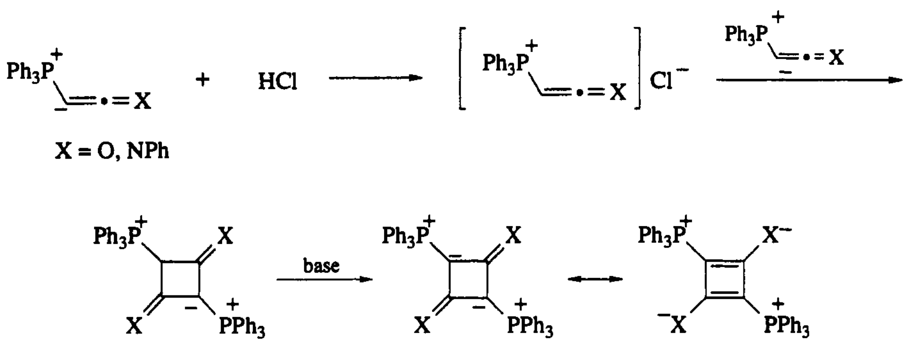
*(a) From reaction with halogen compounds*

Oxovinylidene- and iminovinylidene-triphenylphosphoranes react with hydrogen chloride in the molar ratio 2:1, leading to 1,3-dioxo- and 1,3-diimino-cyclobutane derivatives, which can be converted into stable exocyclic bisalkylidenephosphoranes by sodium bis(trimethylsilyl)amide (equation 102).

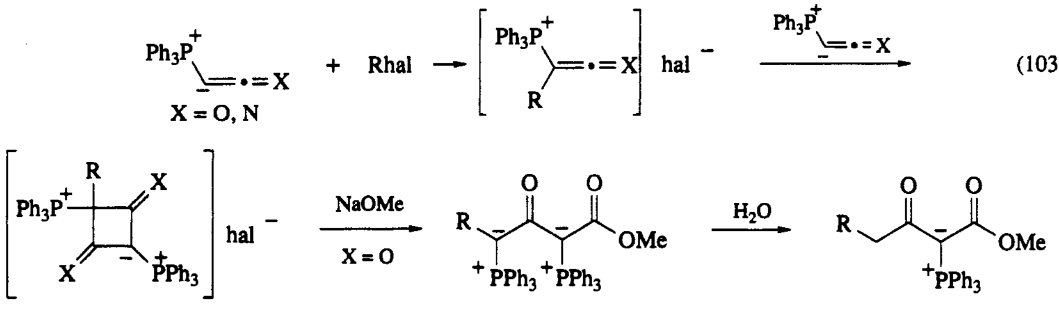
The resulting dimers of the original phosphacumulene ylides are of particular interest because one of their resonance forms represents another type of 'push–pull' cyclobutadiene.

Reactions of oxo- and imino-vinylidenetriphenylphosphoranes with alkyl halides also proceed *via* nucleophilic substitution, which is followed by a [2 + 2] cycloaddition yielding four-membered ylide phosphonium salts (equation 103), which can also be generated from the previously mentioned dimers and alkyl halides. Ring opening of the resulting ylide phosphonium salts with sodium methoxide gives bisylides. Since the ylide flanked by two carbonyl groups in the bisphosphoranes is much more inert than that adjacent to only one CO group, these compounds are easily hydrolyzed by water to monoylides.

The reaction of oxovinylidenetriphenylphosphorane or its dimer with aromatic carboxylic acid chlorides leads not to cyclobutanedione derivatives but to pyrone compounds, which can be converted to open chained bisphosphoranes with sodium methoxide (equation 104).[205] If the acid chlorides carry an

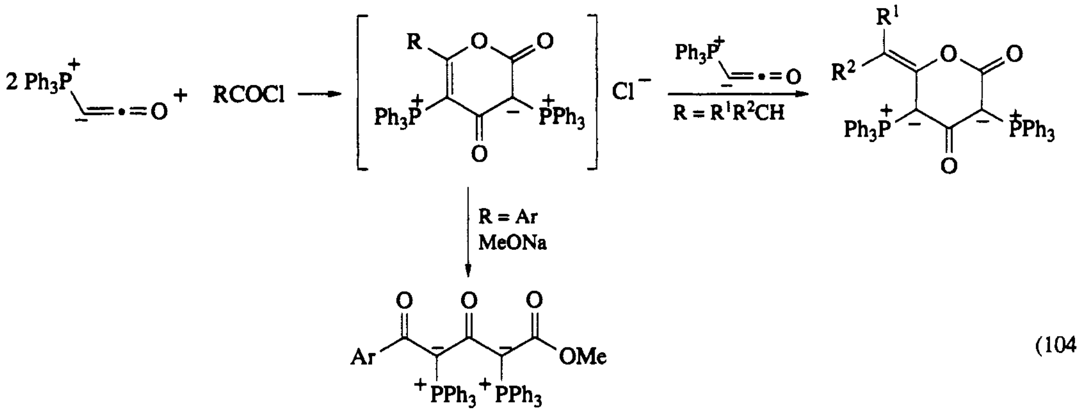


(102)



(103)

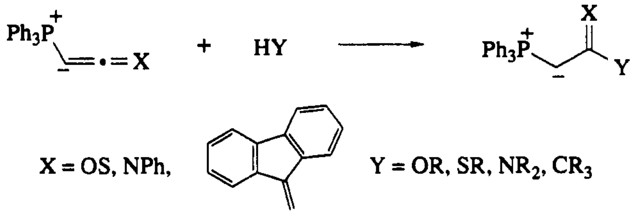
α-H atom, the resulting ylide phosphonium salts are deprotonated at the vinyl position by excess starting ylide yielding exocyclic bisylides.



(104)

### (b) From reactions with acidic compounds

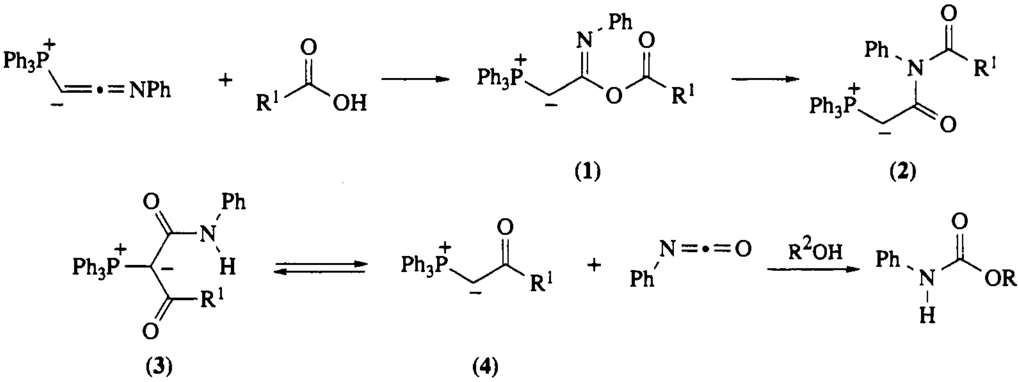
In the reaction of OH-, NH-, SH- and CH-acidic compounds with phosphacumulene ylides the anion $Nu^-$ of the initially formed phosphonium salt (*cf.* equation 101) is so nucleophilic, that addition of the anion to give a new alkylidenephosphorane is faster than cycloaddition of a second mole of starting ylide (equation 105).[204,206]



(105)

According to the difference of the ylides in nucleophilicity (NR > O > S) iminovinylidene- and oxovinylidene-phosphorane smoothly add alcohols, thiols and acidic NH compounds, while thioxovinylidenephosphorane reacts readily with thiols and phenols, less rapidly with aliphatic alcohols and does not react with NH-acidic compounds. Strongly activated $CH_2$ groups add readily to iminovinylidenephosphoranes, less rapidly to oxovinylidenephosphorane and not at all to thioxovinylidenephosphorane. (The fluorenylidene derivative is less reactive than iminovinylidenetriphenylphosphorane and more reactive than the oxovinylidene and thioxovinylidene compounds.) By this method a great variety of alkylidenephosphoranes carrying α-substituents derived from the carboxy group can be synthesized.[206]

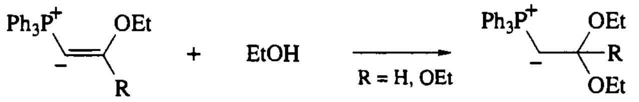
Carboxylic acids react with phenyliminovinylidenetriphenylphosphorane (equation 106) *via* the intermediates (**1**) with formation of the alkylidenephosphoranes (**2**), which, on heating, rearrange in an intramolecular acyl migration to ylides (**3**). By heating (**2**) in the presence of an alcohol the acyl ylides (**4**) and *N*-phenylurethanes are formed.[206,207] The reaction sequence allows the replacement of the OH group in carboxylic acids by the ylide function.



(106)

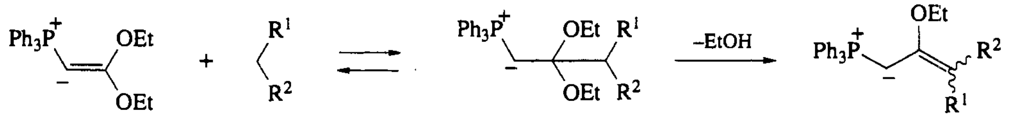
The addition of acidic compounds to phosphacumulene ylides yielding substituted alkylidenephosphoranes is of particular interest in the reaction of those acidic molecules which carry, besides the Y—H bond, a group capable of cyclization with the ylide function formed by addition.[208–215]

Ethoxy- and diethoxy-vinylidenetriphenylphosphorane add alcohols to the C═C bond according to the general scheme described above yielding orthoester phosphoranes (equation 107).[85,216,217]



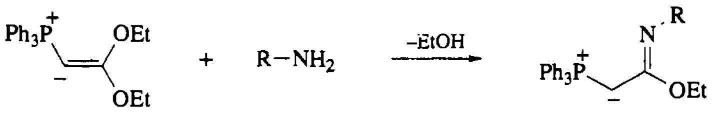
(107)

Because of its enhanced reactivity, diethoxyvinylidenetriphenylphosphorane adds a variety of CH acids, even those which do not react with oxo-, thioxo- and imino-vinylidenetriphenylphosphorane. Irreversible loss of ethanol from the initially formed Michael adduct gives phosphoranes which are vinylogs of β-keto ylides if the starting material is an acidic carbonyl compound (equation 108).[204,216] CH-acidic carbonyl compounds also may add to diethoxyvinylidenetriphenylphosphorane *via* the enolate oxygen, thus leading to orthoester phosphoranes which can undergo intramolecular Wittig reaction.[218]



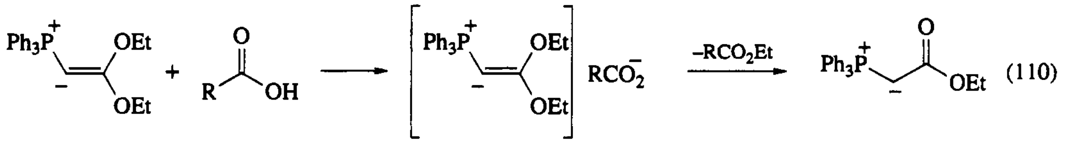
(108)

NH-acidic amines react like CH-acidic compounds. The initially formed Michael adduct loses ethanol giving rise to the formation of ethoxyiminocarbonylmethylenephosphoranes (equation 109).[206]



(109)

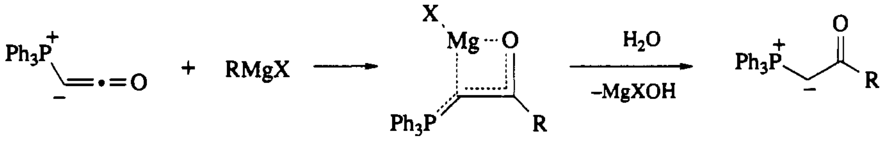
Strongly CH-acidic compounds, carboxylic acids and thiols react with diethoxyvinylidenetriphenylphosphorane not in the described manner but are ethylated by the ylide (*e.g.* equation 110).



(110)

*(c) From reaction with Grignard compounds*

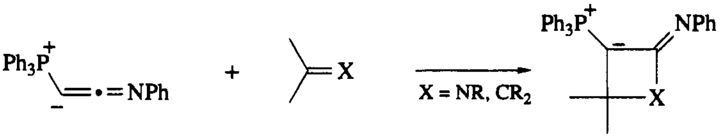
In the reaction of halogen compounds with oxovinylidenetriphenylphosphorane the initially formed phosphonium salt undergoes cycloaddition with a second molecule of the starting ylide. Umpolung of the reactivity of alkyl halides by transformation into the corresponding Grignard compounds, however, results in the reaction type which occurs in the reaction of acid compounds with oxovinylidenetriphenylphosphorane. Grignard compounds and oxovinylidenetriphenylphosphorane yield addition compounds from which, on subsequent hydrolysis, acyl ylides are formed (equation 111).[219,220]



(111)

*(ii) By cycloaddition reactions*

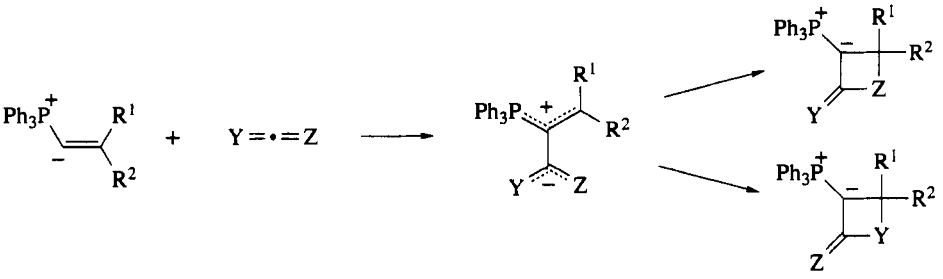
A variety of compounds may undergo cycloaddition at the C=C bond of vinylidenephosphoranes yielding exocyclic ylides.[204,221] [2 + 2] Cycloadditions of *N*-phenyliminovinylidenetriphenylphosphorane to electron poor double bonds of alkenes and imines lead to the formation of four-membered ylides (equation 112).[204,221]



(112)

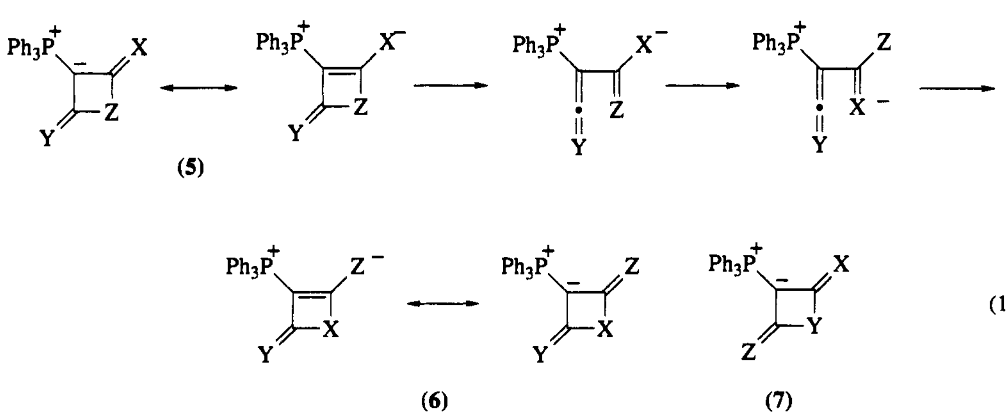
Alkynes however add to the P–C bond of vinylidenephosphoranes. The initially formed phosphacyclobutenes undergo electrocyclic ring opening to afford open chain ylides.[204,221]

Heteroallenes (*e.g.* carbon disulfide, carbon dioxide, carbon oxysulfide, isocyanates, isothiocyanates, ketenes, ketenimines) and vinylidenephosphoranes can form polar intermediates from which two isomeric products may result in a 1,4-cycloaddition (equation 113).[204,221] The direction of the ring closure depends decisively upon the nucleophilic character of Z compared with that of Y.



(113)

In the reaction of oxo-, thioxo- and imino-vinylidenetriphenylphosphorane the initially formed cycloadduct (**5**) may undergo electrocyclic ring cleavage followed by a second ring closure thus affording the rearranged isomer (**6**). The overall reaction sequence amounts to exchange of the exocyclic substituent X with the ring member Z. The isomer (**7**) may rearrange analogously. In one case cycloreversion of the four-membered ring occurred (see preparation of thioxovinylidenetriphenylphosphorane).

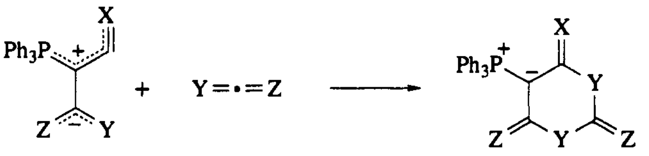


(5)

(6) (7)

(114)

Sometimes [4 + 2] cycloaddition of the dipolar 1:1 intermediate with a second molecule of heteroallene proceeds faster than the 1,4-cyclization, thus leading to six-membered rings (equation 115). Obviously this type of reaction especially occurs if the lifetime of the dipolar intermediate is sufficiently long owing to stabilization of the positive charge. While phenyliminovinylidenetriphenylphosphorane reacts with heteroallenes only in the molar ratio 1:1 the corresponding oxo, thioxo and diethoxy compounds can react both in 1:1 and 1:2 ratio.

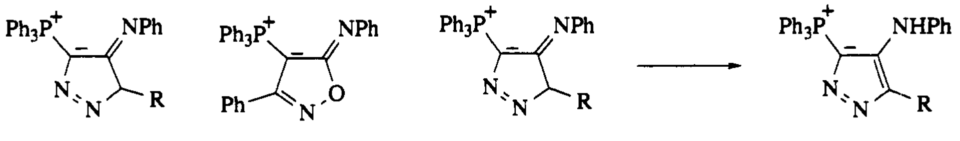


(115)

Diethoxy- and bis(ethylthio)-vinylidenetriphenylphosphorane differ in some instances in their behavior towards heteroallenes from the other vinylidenephosphoranes. The dipolar 1:1 intermediates from diethoxyvinylidenephosphorane and carbon dioxide or carbon disulfide stabilize by migration of an ethyl group to the negative substituent (*cf.* equation 113, $R^1$, $R^2$ = OEt; Y, Z = O or S); on the other hand the 1:2 adducts from the bis(ethylthio) ylide and isocyanates or isothiocyanates do not form six-membered but five-membered rings, which lose triphenylphosphine and hence yield no ylides.[222]

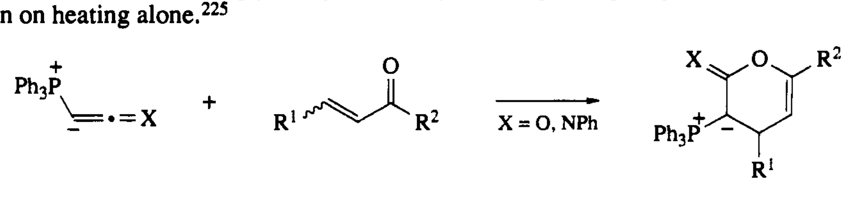
The [2 + 2] cycloaddition and the [4 + 2] addition of vinylidenephosphorane with heteroallenes have been applied to the synthesis of a great variety of four- and six-membered heterocyclic compounds carrying an exocyclic ylide function.[204,221,223]

1,3-Dipolar compounds (*e.g.* azides, nitriloxides and diazo compounds) add to the C=C bond of vinylidenephosphorane, affording five-membered ylidic heterocycles, *e.g.* those based on the 1,2,3-triazole, 1,2-oxazole and pyrazole skeleton from the reactions with *N*-phenyliminovinylidenetriphenylphosphorane (equation 116).



(116)

[4 + 2] Cycloaddition of α,β-unsaturated ketones, acyl ketenes, acyl, thioacyl, imidoyl and vinyl isocyanates, as well as the corresponding isothiocyanates, to the C=C bond of vinylidenephosphoranes leads to the formation of six-membered heterocycles carrying an exocyclic ylide function (*e.g.* equation 117).[204,212,224] In some instances the mentioned thioisocyanates, however, may undergo [2 + 2] cycloaddition at the C=S bond. Interestingly *N*-aryliminovinylidenetriphenylphosphoranes dimerize in a [4 + 2] cycloaddition on heating alone.[225]



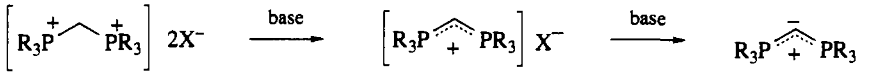
(117)

## 1.6.2 CUMULATED PHOSPHORANES

### 1.6.2.1 Carbodiphosphoranes

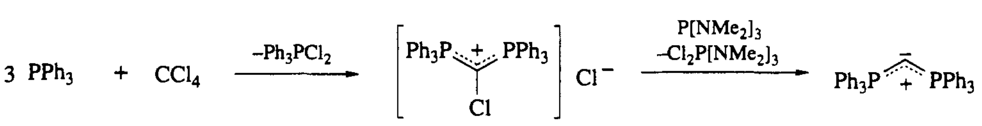
Carbodiphosphoranes (bistriorgano)phosphoranylidenemethanes, hexaorganocarbodiphosphoranes) may be generated from suitable phosphonium salt precursors by dehydrohalogenation or dehalogenation.[226] Since the first synthesis of hexaphenylcarbodiphosphorane, a series of symmetrical, unsymmetrical, mixed alkyl/phenyl, cyclic and difunctional carbodiphosphoranes have been prepared. Compounds synthesized until 1984 have been listed.[227]

Stepwise deprotonation of methylenebis(triorgano)phosphonium salts with bases yields carbodiphosphoranes *via* intermediate semi-ylide salts, which may also be accessible by alkylation or phosphinolation of corresponding alkylidenephosphoranes (equation 118).[226–228] It depends on the starting phosphonium salt and the base whether the intermediate ylide salts can be isolated or not. Suitable bases are sodium amide, alkali metal hydrides, alkylidenetrialkylphosphoranes, potassium and lithium organyls. For the synthesis of hexaphenylcarbodiphosphorane improved methods have been reported by which this compound may be generated without isolation of the ylide salt and on a large scale.[201,229]



(118)

Hexaphenylcarbodiphosphorane and other carbodiphosphoranes are also available by dechlorination of phosphonium salts (*e.g.* equation 119).[198,226]



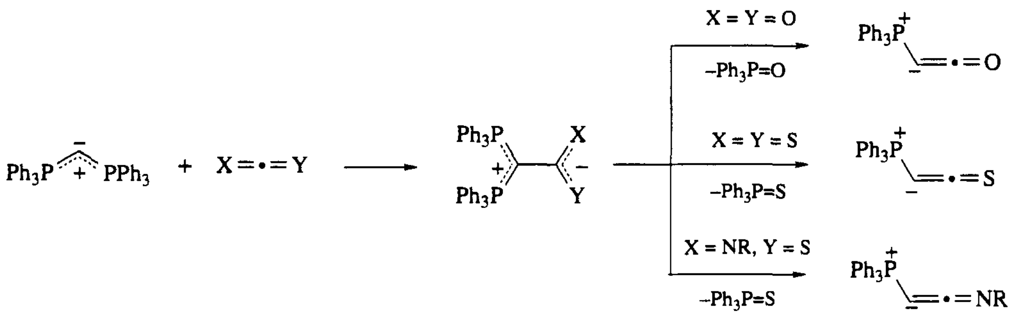
(119)

Hexaphenylcarbodiphosphorane may be stored as a stable adduct formed with sulfur or trimethylchlorosilane, from which it may be regenerated with triethylphosphine or by thermolysis, respectively.[201,202]

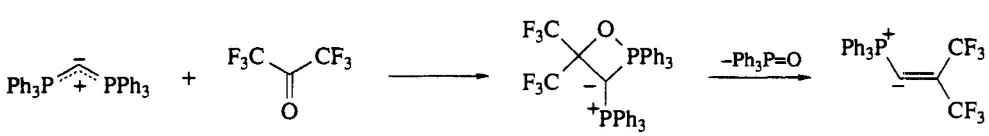
As a consequence of their astonishingly high tendency of formation carbodiphosphoranes spontaneously result in some instances from other bisylide precursors by skeletal rearrangement.[227,230] The stability of carbodiphosphoranes is markedly influenced by the nature of the substituents attached to the phosphorus and in the case of cyclic species also in particular by ring strain. As a consequence of these facts carbanion-stabilizing substituents and ring strain effects may cause prototropic rearrangements to afford conjugated isomeric double ylides.[199,231–234]

### 1.6.2.2 Vinylidenephosphoranes

Hexaphenylcarbodiphosphorane reacts with carbon dioxide, carbon disulfide and isothiocyanates to give betaines whose thermolysis affords oxovinylidene-, thioxovinylidene- and iminovinylidene-triphenylphosphoranes (equation 120).[204,235] The corresponding 2,2-di(trifluoromethyl) compound is obtained when the 1,2-oxaphosphetane resulting from hexaphenylcarbodiphosphorane and hexafluoroacetone (equation 121) is heated.

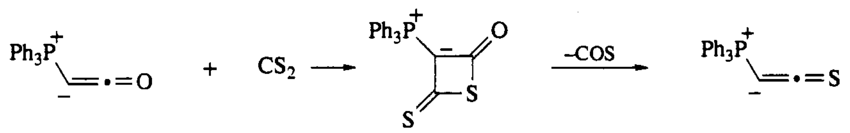


(120)



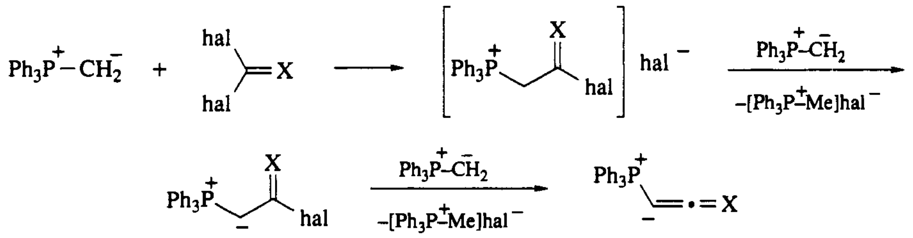
(121)

Thioxovinylidenetriphenylphosphorane is formed when the cycloaddition compound from oxovinylidenetriphenylphosphorane and carbon disulfide decomposes in a cycloreversion (equation 122).[204,235]



(122)

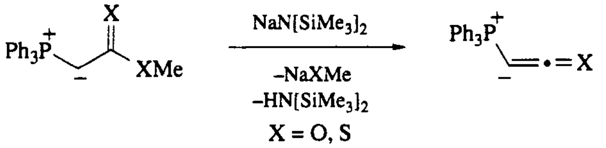
Methylenetriphenylphosphorane reacts with geminal dihalo compounds (isocyanide dichlorides, thiophosgene and 1,1-dihalo-1-alkenes) in the molar ratio 3:1. The initially formed phosphonium salt undergoes transylidation affording the conjugated ylide from which a third molecule of methylenetriphenylphosphorane removes hydrogen halide thus leading to thioxovinylidene-, iminovinylidene- and 1,2-alkadienylidene-phosphoranes, respectively (equation 123).[204,235] The reaction with 1,1-dihalo-1-alkenes requires electron-accepting substituents $R^1$ and $R^2$. The method is not suitable for the synthesis of oxovinylidenetriphenylphosphorane starting from phosgene. Attempts to generate cumulated species $R_3P{=}C{=}SiR_2$ by dehydrohalogenation of the corresponding β-halogenated ylide precursor were not successful.[67i]



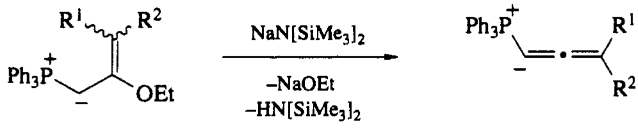
(123)

X = S, NR, $CR^1R^2$; hal = Cl, Br

Reaction of sodium bis(trimethylsilyl)amide with methoxycarbonylmethylenetriphenylphosphorane or its dithio analog leads to β-elimination and formation of oxovinylidene- and thioxovinylidene-triphenylphosphorane, respectively (equation 124).[204,235] The analogous reaction of sodium bis(trimethylsilyl)amide with 2-ethoxyallylidenetriphenylphosphoranes resulting from 2,2-diethoxyvinylidenetriphenylphosphorane and CH acids gives rise to the formation of stable propadienylidenephosphoranes (equation 125).[235]

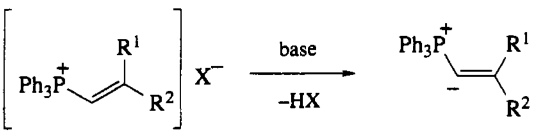


(124)



(125)

Finally vinylidenephosphoranes are accessible by α-deprotonation of vinylphosphonium salts with suitable bases, *e.g.* sodium amide, sodium ethoxide or sodium bis(trimethylsilyl)amide (equation 126).[169,204,235]



(126)

a, $R^1 = R^2 = OEt$; b, $R^1 = H, R^2 = OEt$; c, $R^1 = S$-alkyl, $R^2 = S$-alkyl; d, $R^1 = H, R^2 = NMe_2$

Propadienylidenephosphoranes have been generated by dehydrohalogenation of 2-halogeno-2-propenyl and propargyl phosphonium salts.[235,236]

## 1.7.1 NUCLEOPHILIC HALOGENATION

The formation of halides by the nucleophilic substitution of leaving groups is commonly used in the synthesis of more elaborate structures. The synthesis of inexpensive bulk chemicals like solvents, however, is mostly done by oxidation or addition reactions. Halides are either used as intermediates or are valuable end products. Authors of publications, especially patent literature, often claim one reaction for three or even four halogens. In practice, this rarely holds true and each of the halogens quite often requires different conditions. The usual order of halide nucleophilicity is $I^- > Br^- > Cl^- > F^-$. In dimethylformamide the reverse order $Cl^- > Br^- > I^-$ is observed.[1] This order goes along with the order of the basic strength of the halogens. Thus in some cases the choice of the proper solvent will be the answer to a synthetic problem.

The following chapter deals with the individual halogens separately. A recent survey of the most important methods of preparation of halogen compounds[2] organizes the material in a similar way. This former review also includes tables[3] correlating halogenating agents with the starting materials and halogenated products.

The development in the field of halogenation is not very rapid. Consequently the now almost 30 years old, thoroughly written Volumes 5/3[4] and 5/4[5] of *Houben–Weyl* are still very useful. Fluorination procedures in organic chemistry are developing considerably faster and the field has been reviewed more recently.[6,7]

## 1.7.2 CHLORINATION

The C—Cl bond is less stable than the C—F bond but more stable than the C—Br and the C—I bonds. This means that chlorinated products normally do not suffer from the often undesired instability of bromides or iodides. On the other hand, more severe conditions are normally required to transform the C—Cl bond later in the synthesis when the chloride is not the desired final functionality. If this is no problem, the chloride is the first choice intermediate functionality because chlorine is by far the least expensive and most ready available of all halogens.

### 1.7.2.1 Chlorination of Alkyl Alcohols

The displacement of hydroxy groups by chlorine is of great importance in synthesis.[8] The reaction of hydrochloric acid with tertiary alkyl alcohols proceeds at room temperature within minutes,[9] while secondary alcohols react more slowly and primary alcohols are the least reactive (Scheme 1). A catalyst, usually zinc chloride[10] or phase transfer conditions,[11] is required if the reaction is too slow. Alternatively the use of HMPA as solvent gives good yields of primary halides.[12] Primary alcohols undergo mainly $S_N2$ and tertiary undergo mainly $S_N1$ reactions. The formation of rearrangement and elimination products is a drawback of this reaction. In addition to that problem, chiral alcohols give different degrees of racemization ($S_N1$), inversion ($S_N2$) or retention of configuration. For these and other reasons inorganic acid chlorides like $SOCl_2$, $PCl_3$, $PCl_5$ and $Ph_3PCl_2$ are often employed, as rearrangement products with these reagents are formed only to a small extent.

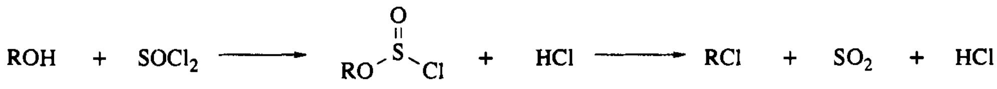
$$ROH + HCl \longrightarrow RCl$$

R = primary
secondary ↓ increasing rate of reaction
tertiary

Scheme 1

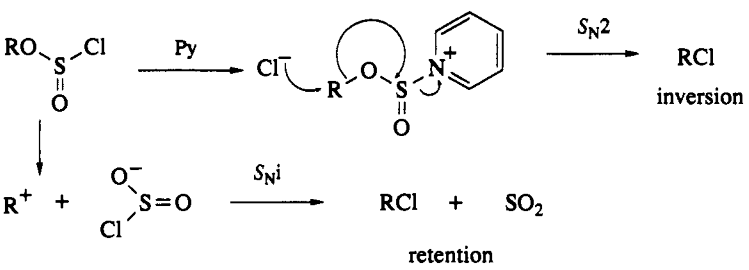
$SOCl_2$ is used extensively in the preparation of chlorides (Scheme 2)[13] although this reaction can give a variety of by-products.[14] Yields are typically in the 70–90% range. In the absence of base retention of configuration is the rule (Scheme 3). This has been explained by an $S_N1$ mechanism or by participation of the solvent.[15] The fact that the secondary chlorosulfite (**1**) gives, on heating, the tertiary chloride (**3**), indicates that an intramolecular single step mechanism is ruled out and an ion pair (**2**) may be involved (Scheme 4).[16] If the reaction is done in the presence of one equivalent of pyridine, inversion ($S_N2$) is likely to occur.[17,18]

$SOCl_2$, like $PCl_3$, still can give products of rearrangement,[19] especially with allylic alcohols. Less rearrangement is observed if DMF[20–23] or HMPA[19] is added. DMF and $SOCl_2$ give the Zollinger reagent (**4**), as in equation (1). Reaction of tertiary alcohols with $PCl_5$ under mild conditions as in equation (2) is a good special method for the synthesis of tertiary chlorides with retention of configuration.[24]

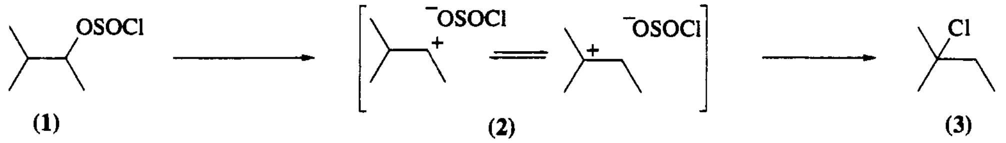


$$ROH + SOCl_2 \longrightarrow RO{-}\overset{O}{\overset{\|}{S}}{-}Cl + HCl \longrightarrow RCl + SO_2 + HCl$$

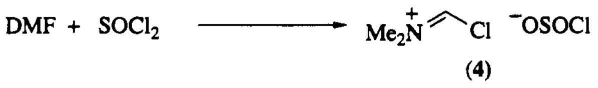
Scheme 2



**Scheme 3**



**Scheme 4**



$$\mathrm{DMF + SOCl_2 \longrightarrow Me_2\overset{+}{N}{=}CHCl\ {}^{-}OSOCl}\quad \mathbf{(4)} \qquad (1)$$

$$\mathrm{ROH + PCl_5 \longrightarrow RCl + POCl_3 + HCl} \qquad (2)$$

For other phosphorus reagents good yields, less rearrangement or both are claimed. The reaction of neopentyl alcohol with $Ph_3PCl_2$ gives 92% yield (Scheme 5).[25,26] The use of oxyphosphonium[27] and phosphorus(III)[28] reagents for the replacement of alcoholic hydroxy groups has been reviewed. The system $Ph_3P$–$CCl_4$ (Scheme 6)[29–31] allows the transformation of labile alcohols like geraniol, lincomycines or sugars. Addition of imidazole to $Ph_3PCl_2$ and to the $Ph_3P$–$CCl_4$ system improves the selectivity and reactivity, respectively.[32] With this technique primary hydroxy groups in carbohydrates are selectively substituted, as exemplified in equation (3). $Ph_3P$–hexachloroacetone is another reagent for the formation of chlorides in high yields, with no rearrangement.[33]

$$\mathrm{R_3P + Cl_2 \longrightarrow R_3PCl_2 \xrightarrow{R'OH} R'Cl + HCl + R_3PO}$$

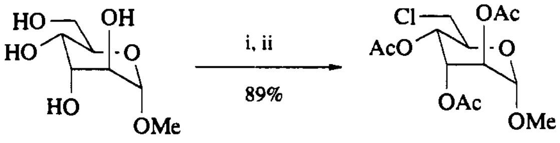
R = Ph, R' = neopentyl; 92%

**Scheme 5**

$$\mathrm{Ph_3P + CCl_4 \longrightarrow Ph_3\overset{+}{P}Cl\ {}^{-}CCl_3 \xrightarrow{ROH}}$$

$$\mathrm{HCCl_3 + Ph_3\overset{+}{P}OR\ Cl^{-} \longrightarrow RCl + Ph_3PO}$$

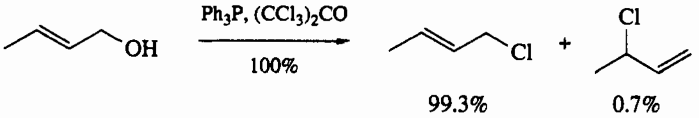
**Scheme 6**



(3)

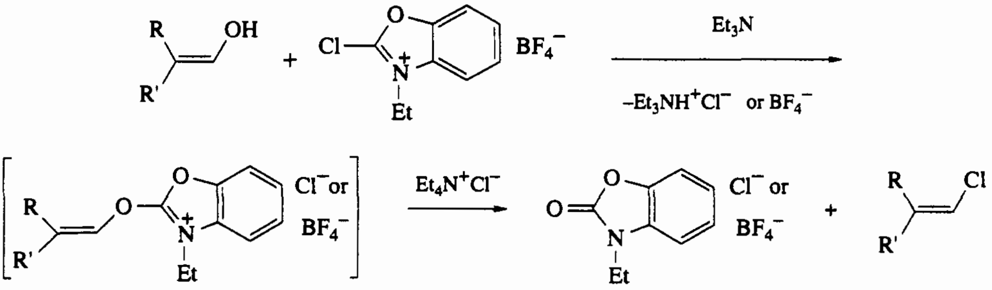
i, $Ph_3PCl_2$, imidazole; ii, $Ac_2O$, pyridine

The conversion of allylic alcohols into chlorides is complicated by the competition of $S_N2$ and $S_N2'$ reactions (equation 4). $SOCl_2$ and $PCl_3$ give mainly $S_N2'$ reactions.[34] With $Ph_3P$–$CCl_4$[35] or $MeSO_2Cl/LiCl$[36] mainly normal $S_N2$ products are formed.



(4)

Alkyl alcohols[37] or enolizable aldehydes are converted in a stereospecific manner to alkyl chlorides or vinyl chlorides in good yields on treatment with a Mukaiyama-type chlorobenzoxazolium salt (Scheme 7).[38] The very good activation of hydroxy groups by the Mitsunobu procedure may be useful in some difficult cases (Scheme 8).[39–42]



**Scheme 7**

$$\mathrm{ROH} \xrightarrow{\text{i, ii}} \mathrm{RCl}$$

i, $EtO_2CN{=}NCO_2Et$, $Ph_3P$; ii, $Cl^-$

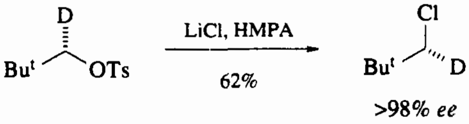
**Scheme 8**

The leaving group is not $OH^-$ but $H_2O$ or $OR^-$. It is a common feature of all the above reactions that the activated species is not isolated. Chlorination of isolated activated alcohols is the subject of the next section.

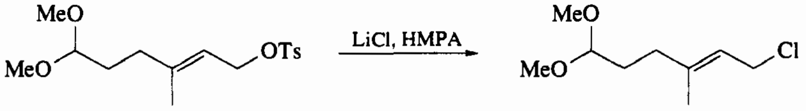
## 1.7.2.2 Chlorination of Alkyl Alcohol Derivatives

$OH^-$ is not a satisfactory leaving group. A sufficient activation is needed to allow nucleophilic displacements. Tosylates, mesylates, triflates, sulfates and other esters of sulfuric and sulfonic acids are suitable leaving groups for this purpose. They are generally easy to make and stable enough for isolation or purification. Isolation of a stable intermediate often gives cleaner reactions and products.

Neopentyl tosylate reacts with LiCl in HMPA and gives the chloride with clean inversion without rearrangement (equation 5).[43] Another example of this reaction is the conversion of allylic tosylates to chlorides without rearrangement or reaction of the sensitive acetal (equation 6).[44] Dimethylaminopyridine is a useful catalyst for the transformation of hydroxy compounds to chlorides with tosyl chloride.[45]

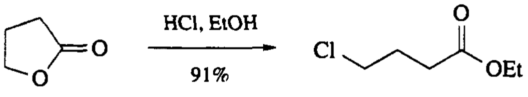


(5)



(6)

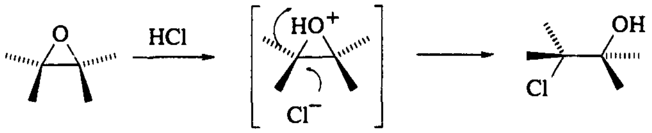
The opening of γ-lactones with alcoholic hydrogen chloride (equation 7) is a useful example of the otherwise rare cleavage of carboxylic esters to alkyl chlorides.[46]



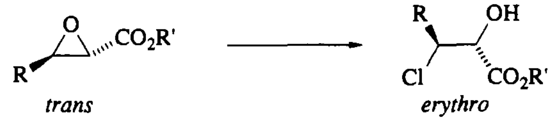
(7)

### 1.7.2.3 Chlorination of Epoxides

The cleavage of dialkyl ethers with hydrogen chloride is rarely successful. A special case is the cleavage of epoxides (Scheme 9), which, due to ring strain, are much more reactive than open chain or larger ring ethers. The mechanism is $S_N2$. This results in formation of a *threo*-chlorohydrin from a *cis*-epoxide and an *erythro* product from a *trans*-epoxide. The regioselectivity of the reaction is satisfactory if one of the two carbon centers can stabilize a positive charge better than the other. An example for good regioselectivity is the opening of epoxy esters (Scheme 10). In the absence of strong electronic effects, hard to predict mixtures of the two possible chlorohydrins are formed.

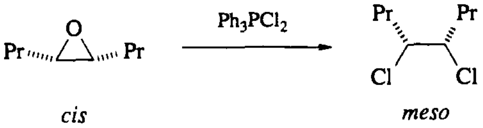


**Scheme 9**



**Scheme 10**

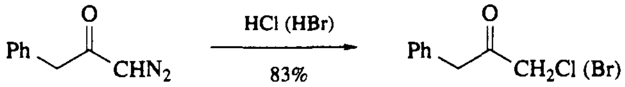
The conversion of epoxides to vicinal dichlorides has been done with $SOCl_2$ and pyridine,[47] $Ph_3P–CCl_4$[48] or $Ph_3PCl_2$.[49] Symmetric *cis*-epoxides give *meso*-dichlorides (equation 8), and the corresponding *trans*-epoxides give D,L-dichlorides. This is a two-step mechanism involving an intermediate chlorohydrin. Two $S_N2$ reactions give inversion at both carbon atoms.



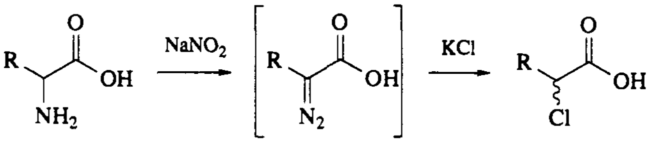
(8)

### 1.7.2.4 Chlorination of Diazo Ketones

Diazo ketones give α-chloro ketones on treatment with hydrogen chloride (equation 9).[50] Diazotization of α-amino acids in the presence of an excess of chloride gives α-chloro acids (Scheme 11).[51] The configurational identity of the amino acids is lost with the achiral diazo intermediate. The reaction becomes useful in cases where the amino acid is easily available and the chloride is not.



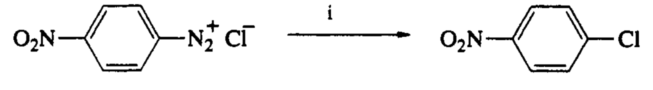
(9)



**Scheme 11**

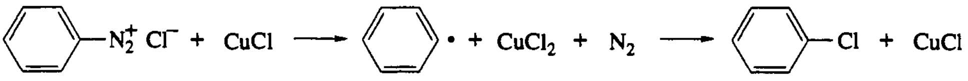
### 1.7.2.5 Chlorination of Diazonium Salts

Phenolic hydroxy groups undergo $S_N$Ar reactions only if the aromatic ring is activated by electron-withdrawing substituents. The replacement of nitrogen in aromatic diazonium salts with hydrogen chloride is by far more common.[52] If the catalyst is copper(I) or copper(II) chloride it is called the Sandmeyer reaction. With copper as catalyst it is called the Gattermann reaction. The choice of catalyst and conditions influences the yields (equation 10).[53] The scope of the reaction is wide. These reactions are useful not only for the formation of aryl chlorides but also of aryl bromides (see Section 1.7.3.5). The synthesis permits the introduction of chlorine with good yields in positions where direct chlorination fails. The mechanism (Scheme 12) is believed to involve a reduction of the diazonium ion to an aryl radical by the copper(I) ion. In the next step the aryl radical reduces copper(II) chloride with aryl–chlorine bond formation.[54]



(10)

i, CuCl, acid, 60% or $CuCl_2$, neutral, 85%

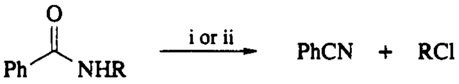


**Scheme 12**

The isolation of the diazonium salt is not always necessary. Several procedures allow the preparation of aryl chlorides from aromatic amines in one step.[55–57]

### 1.7.2.6 Other Chlorinations

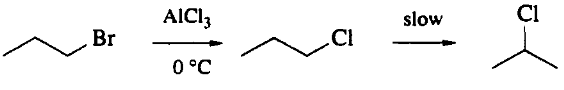
*N*-Alkylamides form alkyl chlorides upon treatment with $PCl_5$[58] or $SOCl_2$.[59] Benzamides give better results than aliphatic amides (Scheme 13), with yields sometimes in the region of 80%.



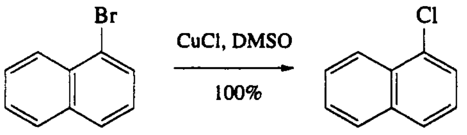
i, $PCl_5$; ii, $SOCl_2$

**Scheme 13**

The replacement of other halogens by chlorine is in most cases a devaluation of the more valuable starting material. If necessary (*e.g.* isotopic labeling), it can be done with LiCl,[60] $AlCl_3$ (equation 11)[61] or copper(I) chloride (equation 12).[62]

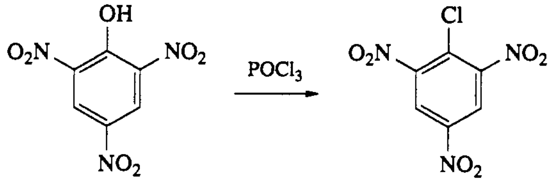


(11)



(12)

Substitution of phenolic hydroxy groups is possible if the aromatic ring is activated by electron-withdrawing substituents, as in picric acid (equation 13).[63] The intermediate pyridinium picrate reacts with $POCl_3$ in an $S_N$Ar mode.



(13)

## 1.7.3 BROMINATION

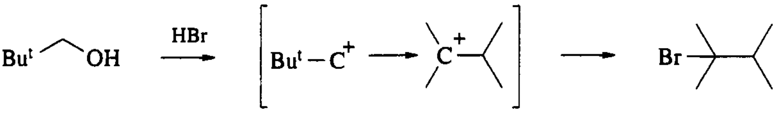
The C—Br bond is less stable than the C—Cl and C—F bonds. Only the C—I bond is weaker. Organic bromine chemistry is strongly related to organic chlorine reactions. On average brominated compounds are two orders of magnitude more reactive than the chlorinated analogs. Brominated intermediates are often not stable enough for storage or even isolation. On the other hand much milder reaction conditions are required for further transformations of the C—Br bond. In laboratory scale preparations the higher reactivity is often more important than storage or cost considerations. Moreover, smaller brominated molecules have a higher boiling temperature than the chlorinated analogs, so the former are often more easy to handle at atmospheric pressure. Distillation of the less stable bromine compounds may be more critical.

Brominated derivatives are especially useful as precursors for organometallic compounds or free radicals.

### 1.7.3.1 Bromination of Alkyl Alcohols

The substitution of alcoholic hydroxy groups with hydrogen bromide appears to be more common than that with hydrogen chloride.[8] Hydrogen bromide is used as a 48% aqueous solution with[64] or without[65] conc. $H_2SO_4$ in acetic acid,[66] or gaseous.[67]

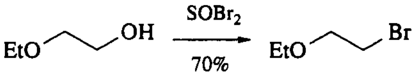
Primary alcohols prefer an $S_N2$ mechanism. When this mechanism is hindered by steric bulk, the Wagner–Meerwein rearrangement competes with substitution (Scheme 14). Secondary and tertiary alcohols follow an $S_N1$ pathway. The intermediate carbonium ion has the tendency to isomerize to a more stable cation.



Scheme 14

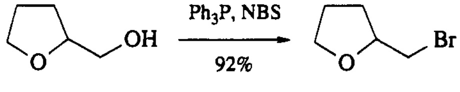
The use of $PBr_3$[68] avoids rearrangement to some extent, but $PBr_3$ is less easily available than hydrogen bromide. $PBr_5$ can also replace hydroxy groups with bromine. It is, however, even more expensive and difficult to handle than $PBr_3$.

The use of $SOBr_2$ is comparatively much less common than the use of the analog $SOCl_2$. $SOBr_2$ is expensive and less stable than $SOCl_2$, but it gives clean reactions with primary alcohols (equation 14).[69]



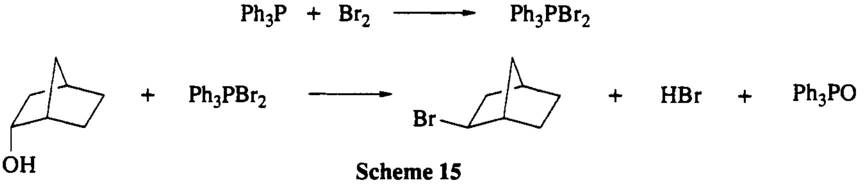
(14)

An alternative to the above-mentioned reagents is the combination of NBS or 1,3-dibromo-5,5-dimethylhydantoin with $Ph_3P$ in DMF (equation 15).[70] In carbohydrate chemistry this reagent gives primary bromides in >70% yield.

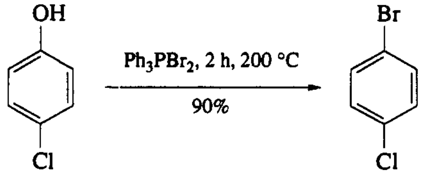


(15)

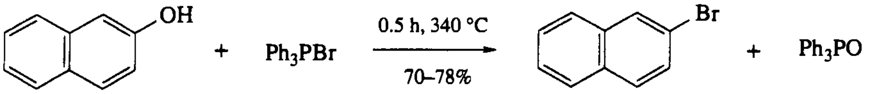
$Ph_3P$ forms with $Br_2$ the very useful brominating reagent $Ph_3PBr_2$. This can replace aliphatic hydroxy groups without rearrangement or elimination (Scheme 15).[71] Another remarkable reaction of this reagent is the substitution of phenolic hydroxy groups, even if they are not activated (equations 16 and 17).[25,72] The high temperature required for this substitution limits the scope of this reaction, however.



Scheme 15

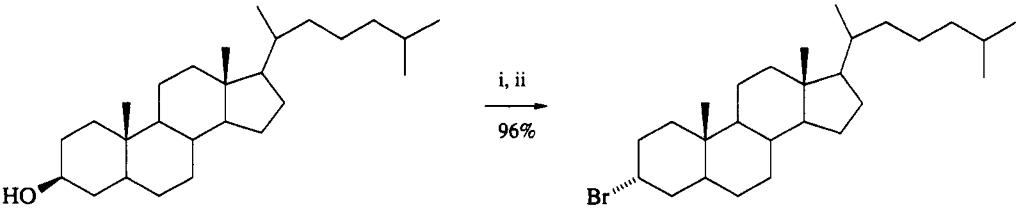


(16)



(17)

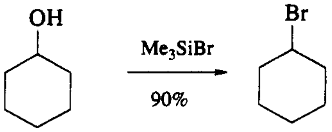
The system of $Ph_3P$–diethyl azodicarboxylate–hydroxy compound–LiBr allows the formation of alkyl bromides under mild conditions (equation 18).[40–42] An $S_N2$-type displacement of an intermediate alkoxyphosphonium species is generally assumed. Hindered alcohols such as menthol do not give bromides with the Mitsunobu procedure.



(18)

i, $Ph_3P$, $EtO_2CN{=}NCO_2Et$; ii, LiBr, 20 °C

Good yields of alkyl bromides result from the treatment of alcohols with $Me_3SiBr$ (equation 19)[73] or $Me_3SiCl$ and LiBr.[74,75]

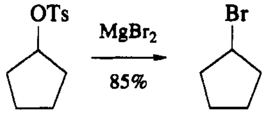


(19)

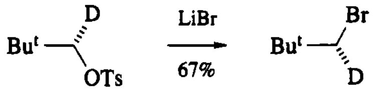
### 1.7.3.2 Bromination of Alkyl Alcohol Derivatives

The above-mentioned reactions for the introduction of bromine always involve an activation of the alcohol as the first step. In some cases it can be useful to isolate the activated intermediate. The reactions of alkyl mesylates or tosylates with $MgBr_2$ give alkyl bromides under mild conditions with good yields (equation 20).[76] Neopentyl tosylate with LiBr in HMPA gives neopentyl bromide in 67% yield (equation 21).[43] Complete inversion with little or no rearrangement is observed in this difficult case.

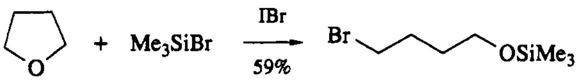
Cleavage of dialkyl ethers with $Me_3SiBr$ is strongly catalyzed by 0.1 equiv. of IBr (equation 22).[77] This makes possible synthetic applications which were previously ruled out by low reactivity.



(20)



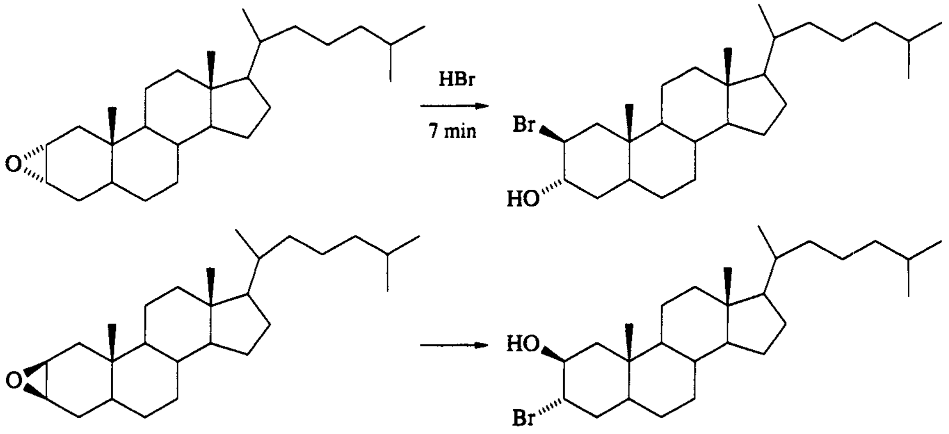
(21)



(22)

### 1.7.3.3 Bromination of Epoxides

The reaction of epoxides with hydrogen bromide gives bromohydrins. The mechanism is $S_N2$ as for the analogous chlorination (see Section 1.7.2.3). The cleavage of epoxy cholestanes with hydrogen bromide (Scheme 16) demonstrates the stereochemical features of the reaction.[78] Diaxial opening of the epoxide ring following the Fürst–Plattner rule is the preferred reaction. Bromohydrins formed this way with excellent stereospecificity can undergo further bromination to dibromides. The replacement reactions are most favored when the centers of the reaction are coplanar.



Scheme 16

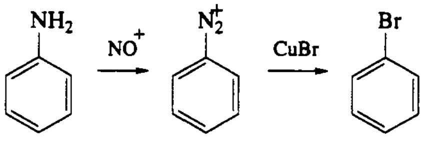
### 1.7.3.4 Bromination of Diazo Ketones

Diazo ketones are transformed to α-bromo ketones on treatment with hydrogen bromide (equation 9).[79]

### 1.7.3.5 Bromination of Diazonium Salts

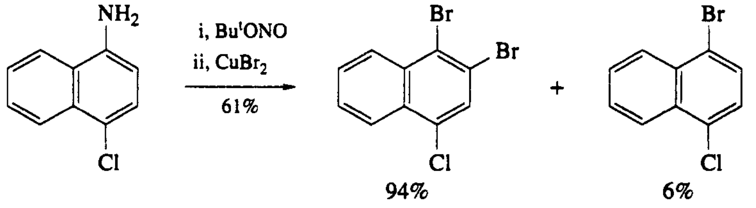
The replacement of phenolic hydroxy groups with $Ph_3PBr_2$ (equations 16 and 17) requires 200 °C or more (see Section 1.7.3.1). The transformation of anilines to bromides *via* diazonium salts is a much more general reaction.[52] Copper(I) or copper(II) bromide is the catalyst in case of the Sandmeyer reaction. If copper is used, the reaction is called the Gattermann reaction. These reactions are also known with the analogous chlorine reagents (see Section 1.7.2.5). Yields are in the 90% range and the scope of the reaction is wide. The mechanism is believed to be analogous to the formation of chlorides (Scheme 17).[54]

Isolation of the intermediate diazonium salt can be avoided in many cases. Treatment with *t*-butyl nitrite followed by $CuBr_2$ can give oxidative bromination in addition to replacement of the diazo group

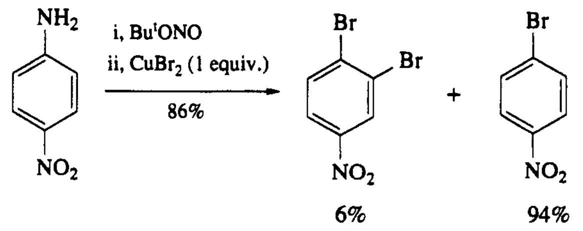


**Scheme 17**

(equations 23 and 24).[57,80] Several other procedures have been described for the preparation of aryl bromides from aromatic amines in one step.[55]



(23)



(24)

### 1.7.3.6 Other Brominations

Brominated compounds are more reactive than the analogous chlorinated compounds. Accordingly it is sometimes necessary to exchange chlorine for bromine. This can be achieved by an equilibrium process, called the Finkelstein reaction, if it is possible to shift the equilibrium to the brominated product (Scheme 18). Primary alkyl chlorides react with ethyl bromide in the presence of *N*-methyl-2-pyrrolidone and metal bromides to give alkyl bromides (Scheme 19).[81] Alkyl iodides do not exchange with HBr under normal conditions. The equilibrium is pushed to the alkyl bromide if $I^-$ is selectively removed from the reaction by oxidation with $HNO_3$ to $I_2$ (Scheme 20).[82] An equimolar mixture of HCl and HBr in the presence of $HNO_3$ gives the alkyl bromide as the major product.

$$\mathrm{RCl} + \mathrm{Br}^- \rightleftharpoons \mathrm{RBr} + \mathrm{Cl}^-$$

**Scheme 18**

i, *N*-methyl-2-pyrrolidone, MBr

**Scheme 19**

$$\mathrm{RI} + \mathrm{Br}^- \rightleftharpoons \mathrm{RBr} + \mathrm{I}^-$$

$$\mathrm{HNO_3} + \mathrm{I}^- \longrightarrow 0.5\,\mathrm{I_2}$$

**Scheme 20**

Tertiary amines are cleaved with BrCN to give an alkyl bromide and a disubstituted cyanamide (Scheme 21). This process is called the von Braun reaction. Many examples have been reviewed.[58,83] Tertiary amines with different R groups cleave so that the most reactive alkyl bromide is formed. Benzyl and allyl cleave better than alkyl, lower alkyl cleaves better than higher alkyl and aryl is not cleaved at all. The mechanism involves an intermediate *N*-cyanoammonium species, which is substituted by bromide anions (Scheme 22).[84]

$$\mathrm{R_2NR' + BrCN \longrightarrow R'Br + R_2NCN}$$

**Scheme 21**

$$\mathrm{R_3N + BrCN \longrightarrow [Br^- + R_3\overset{+}{N}CN] \longrightarrow RBr + R_2NCN}$$

**Scheme 22**

### 1.7.4 IODINATION

The C—I bond is very unstable and more reactive than C—Br, C—Cl and C—F bonds. Iodine is the most expensive of the common halogens and is much less frequently used in synthesis than bromine, chlorine or fluorine. Organometallic reactions proceed with iodinated aliphatic or aromatic compounds more easily than with the other halogens. Noble metal catalysis with palladium complexes is most effective with iodinated compounds. A useful synthetic procedure is the facile reduction of iodinated derivatives under mild conditions. Replacement of iodine by hydrogen at an $sp^3$ carbon is an exothermic reaction with $\Delta H = -25$ kJ mol$^{-1}$.

Selective reactions of iodide are possible in the presence of other functional groups, including other halides.

#### 1.7.4.1 Iodination of Alkyl Alcohols

Alcohols are converted to iodides with HI in good to high yields (Scheme 23).[8] HI is often prepared *in situ* from potassium iodide and phosphoric acid.[85] The substitution reaction competes with reduction of the alkyl iodide to the alkane.[86] Another problem, namely rearrangement, is common to all acid-catalyzed reactions of alcohols; HI is no exception to this rule.

$$\mathrm{ROH \xrightarrow{HI} RI}$$

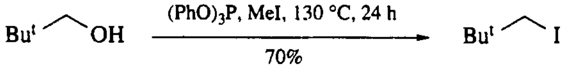
**Scheme 23**

A method to avoid unwanted rearrangements involves the use of $PI_3$, which is normally generated from white or red phosphorus and $I_2$ (Scheme 24).[87] This method also suffers from the reducing power of iodide as an alternative pathway.

$$\mathrm{ROH \xrightarrow{red\ P,\ I_2} RI}$$

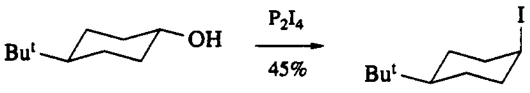
**Scheme 24**

Phosphite diiodide converts alcohols to iodides.[88] This reagent has been used much less often than the corresponding dibromides or dichlorides. Phosphite methiodides give better yields of iodides in the reaction with primary, secondary and tertiary alcohols and are simple to use.[89] Neopentyl iodide is isolated in 70% yield from the reaction of triphenyl phosphite, neopentyl alcohol and methyl iodide (equation 25). This reaction is remarkable considering the severe steric bulk of the neopentyl group which often makes rearrangement become the major process.



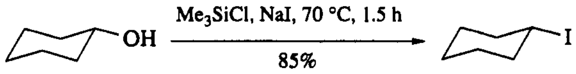
(25)

Diphosphorus tetraiodide is a valuable reagent for the regioselective synthesis of iodoalkanes from alcohols. The reaction occurs stereoselectively in the case of secondary alcohols (equation 26).[90]

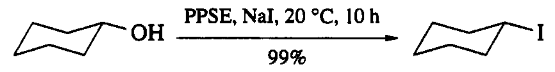


(26)

Trimethylsilyl iodide converts alcohols to iodides.[91] The disadvantage of this method is the expensive reagent, which is avoided if trimethylsilyl chloride and sodium iodide are used instead (equation 27).[92,93] Trimethylsilyl polyphosphate (PPSE), which is prepared from hexamethyldisiloxane and phosphorus pentoxide, also activates alcoholic hydroxy groups for substitutions with iodide anions (equation 28).[94]

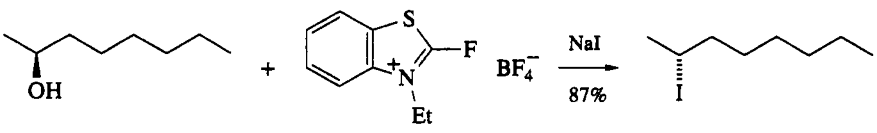


(27)



(28)

Activation of alcohols with fluorobenzothiazolium[95] or fluoropyridinium salts,[96] as well as with carbodiimidinium iodide,[97] allows the nucleophilic substitution with iodide to occur under mild conditions with inversion of configuration (equation 29).

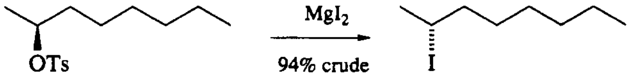


(29)

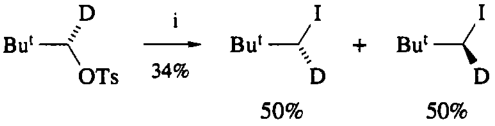
## 1.7.4.2 Iodination of Alkyl Alcohol Derivatives

Iodide is a very effective nucleophile, although it is still not able to substitute the hydroxy group without activation. The activated intermediates are not isolated in most cases. The iodinated products, however, suffer sometimes from a low stability which limits the period of storage. In such and other cases it may be best to use activated derivatives of alcohols as the stable intermediate.

A general method for the synthesis of alkyl iodides is the reaction of tosylates or methanesulfonates with sodium iodide in acetone or magnesium iodide in diethyl ether (equation 30).[98] The reaction is not always a clean $S_N2$ process. Stereoselectively deuterated neopentyl tosylate, for example, gives with NaI in HMPA only low yields (34%) of the racemic iodide (equation 31).[43] This is in contrast to analogous reactions with bromide and chloride (see Sections 1.7.3.2 and 1.7.2.2), where better yields with complete inversion are observed.



(30)



(31)

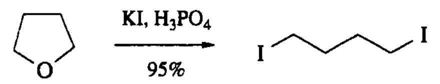
i, NaI, HMPA, 100 °C, 4 h, 80% conversion

## 1.7.4.3 Iodination of Ethers and Epoxides

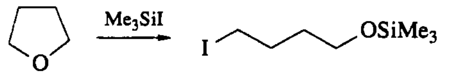
Ethers are cleaved by HI faster than by HBr and HCl (Scheme 25). To prevent the undesirable reducing action of the reagent, KI and phosphoric or polyphosphoric acid are used to generate HI *in situ* (equation 32).[99,100] The ether bond is also cleaved by trimethylsilyl iodide (equation 33).[74]

$$\mathrm{ROR'} + \mathrm{HI} \longrightarrow \mathrm{RI} + \mathrm{R'OH}$$

**Scheme 25**

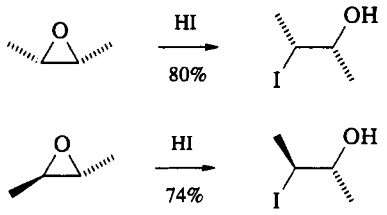


(32)

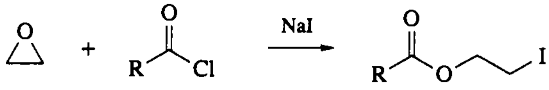


(33)

The release of ring strain in epoxides is probably responsible for the high reactivity of these special ethers. HI opens epoxides under mild conditions stereospecifically to iodohydrins (Scheme 26).[101] The mechanism is similar to the reaction of bromide with epoxides (see Section 1.7.3.3). It should be noted, however, that reduction of epoxides to alkenes may occur if vicinal diiodides are intermediately formed, which can lose $I_2$ under the reaction conditions. With the combination of acyl chloride and NaI unstable diiodides are avoided and 2-iodoethyl esters are formed from oxiranes (Scheme 27).[102]



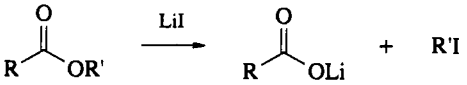
Scheme 26



Scheme 27

### 1.7.4.4 Iodination of Carboxylic Esters

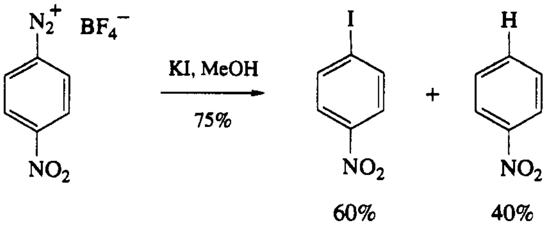
LiI in boiling pyridine or other weak nucleophilic bases can cleave alkyl esters to alkyl iodides and lithium carboxylates (Scheme 28). The reaction is mainly used for mild, aprotic cleavage of esters to carboxylates. The high degree of dissociation for LiI and the nucleophilic strength of the iodide ion explain the reaction with esters, which is not useful with the other halides. Trimethylchlorosilane and sodium iodide also give alkyl iodides from esters.[93]



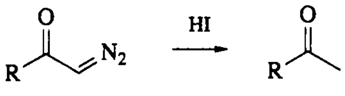
Scheme 28

### 1.7.4.5 Iodination of Diazonium Salts

The transformation of aryl diazonium salts by aryl iodides does not require catalysis by copper or its salts (see Sections 1.7.2.5 and 1.7.3.5). A drawback is unwanted reduction with removal of functionality (equation 34).[103] Diazo ketones are reduced to ketones with HI and do not give halogenated products (Scheme 29).[104]



(34)



Scheme 29

### 1.7.4.6 Other Iodinations

Halide exchange from the lower halides to iodine is often desirable due to the higher reactivity of iodides in nucleophilic substitutions, reductions, organometallic or radical reactions (Scheme 30). Conversion of chlorides and bromides to iodides with sodium iodide in acetone is called the Finkelstein reaction. This halide exchange is an equilibrium process, which is shifted to the iodinated products due to precipitation of the less soluble sodium bromide or chloride from acetone. Best results are obtained when the reaction mixture is free of water.

$$\mathrm{RX} \xrightarrow{\mathrm{I}^-} \mathrm{RI}$$

Scheme 30

## 1.7.5 FLUORINATION

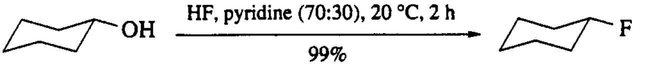
The C—F bond has a very high dissociation energy (>450 kJ mol$^{-1}$) and it is accordingly seldom used as an intermediate functionality. Poly- and per-fluorinated hydrocarbons are useful due to their inertness and physical properties. Monofluorinated analogs of biologically important compounds often show very different activities to the parent compounds. Fluoroacetic acid, for instance, is highly toxic with an estimated lethal dose of 2–5 mg kg$^{-1}$ and is used as a rodenticide.[105] The discovery that fluorinated cortisol is 10 times more potent than the natural parent compound[106] came totally unexpectedly and was a contradiction to the belief that the natural hormone has the highest achievable potency. Fluorine has several interesting properties which make it a potentially useful substituent in drug molecules. The steric requirements of fluorine and hydrogen are very similar. The metabolism of fluorinated drugs is often inhibited due to the strong C—F bond. The electronegativity of fluorine compared with hydrogen may increase receptor affinity. A recent review[7] focuses on the preparation of biologically active organofluorine compounds.

Formation of the C—F bond mostly requires conditions different from all other carbon–halogen bond formations.

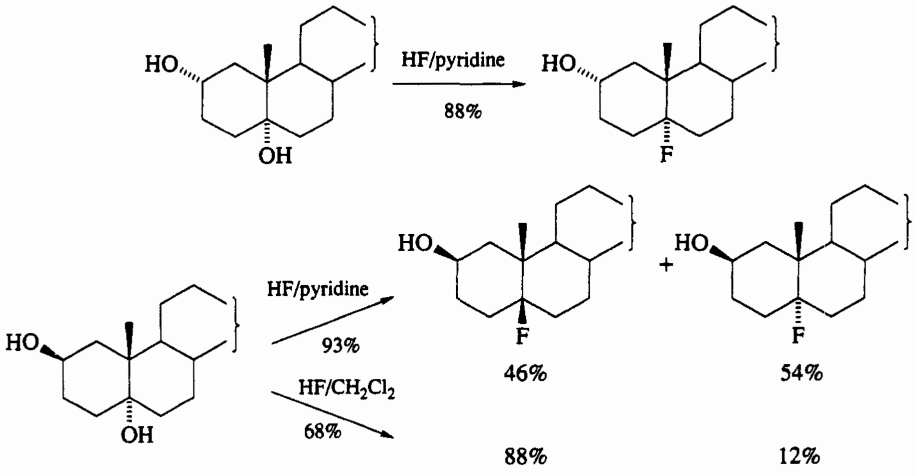
### 1.7.5.1 Fluorination of Alkyl Alcohols

Hydrogen fluoride is only of limited value for the conversion of alcohols to fluorides.[107] Anhydrous HF is a dangerous low boiling liquid (b.p. 19.5 °C), which can cause painful injuries if traces of the acid come into contact with the skin. Only tertiary and secondary alcohols give fluorides, accompanied by elimination products and ethers. Olah's reagent, a mixture of 70% HF and 30% pyridine, is much more convenient to use and often gives better yields (equation 35).[108] The reagent contains a poly(hydrogen fluoride) species, in which each fluorine atom is surrounded by four hydrogen atoms. The poly(hydrogen fluoride) is in equilibrium with some monomeric hydrogen fluoride. The reagent is stable up to 55 °C and often overcomes the need to carry out reactions with corrosive and hazardous anhydrous HF under pressure. The mechanism of the reaction is not clear. In steroid chemistry retention, inversion and scrambling of configuration is observed in related cases with tertiary alcohols (Scheme 31).[109]

$SF_4$ and diethylaminosulfur trifluoride (DAST) give alkyl fluorides not only from tertiary and secondary, as with HF, but also from primary alcohols (equation 36). Reactions with gaseous, corrosive $SF_4$ (b.p. −38 °C) usually require temperatures of 20–100 °C. The special equipment needed for reactions with toxic gases under pressure make the use of $SF_4$ inconvenient. The introduction of DAST has removed the handling problems. DAST is a liquid reagent made from $SF_4$ and trimethylsilyldiethyl-



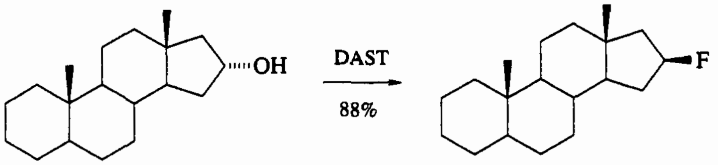
(35)



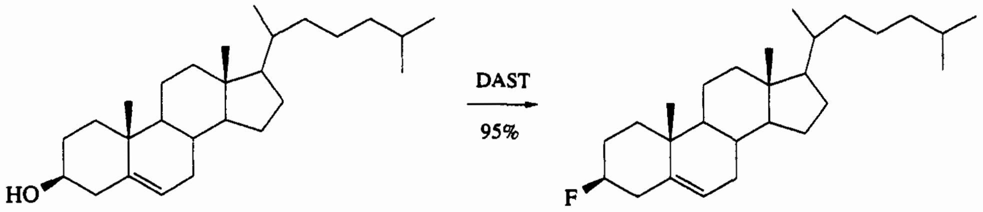
**Scheme 31**

amine. It gives fluoroalkanes from alcohols at lower temperatures (–50 to –78 °C) than $SF_4$ and is safe below 40 °C.[110] Carbenium ion type rearrangement and elimination appear less problematic with DAST than with HF reagents. The stereochemistry of the reaction, however, is still not uniform. In the absence of other directing factors an $S_N2$-type mechanism with inversion of configuration is often observed (equation 37).[111,112] Neighboring group participation, however, results sometimes in retention of configuration (equation 38).[111]

$$n\text{-}C_8H_{17}OH \xrightarrow[90\%]{\text{DAST, -50 °C}} n\text{-}C_8H_{17}F \qquad (36)$$



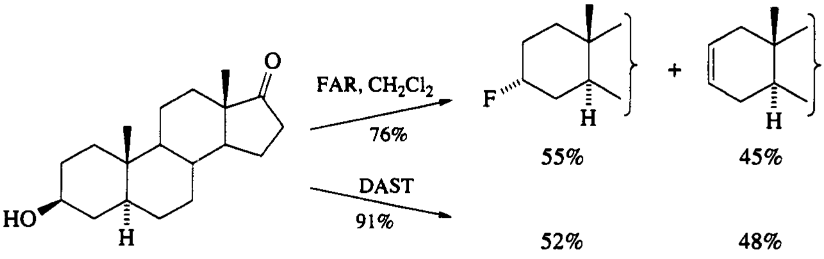
(37)



(38)

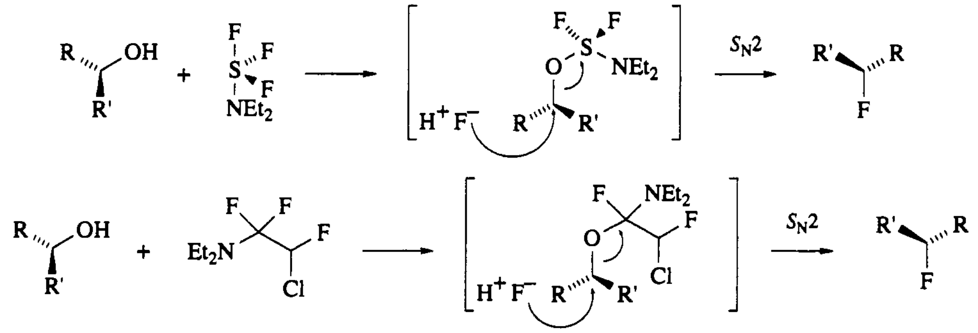
The fluoroalkylamine reagent (FAR) 2-chloro-1,1,2-trifluorotriethylamine gives alkyl fluorides from alcohols in one step and is known as the Yarovenko reagent.[113] This reagent is less reactive than DAST but was used intensively before the introduction of DAST. Rearrangement and elimination are similar with FAR and DAST (equations 39 and 40).[112,114] This may be explained by the similar mechanism. Activation of the alcohol by intermediate formation of ester-type derivatives is followed by $S_N2$-type displacement by fluoride ion (Scheme 32).

A related group of reagents to FAR and DAST is the phenylfluorophosphoranes. The mechanism is believed to be similar but the reactivity increases with the degree of fluorination. While the di- and trifluorophosphoranes require 150 °C for the conversion of primary alcohols to primary fluorides (equation 41),[115,116] tetrafluorophosphorane converts cholesterol to fluorocholesterin with inversion of configuration at 20 °C (equation 42).[117]



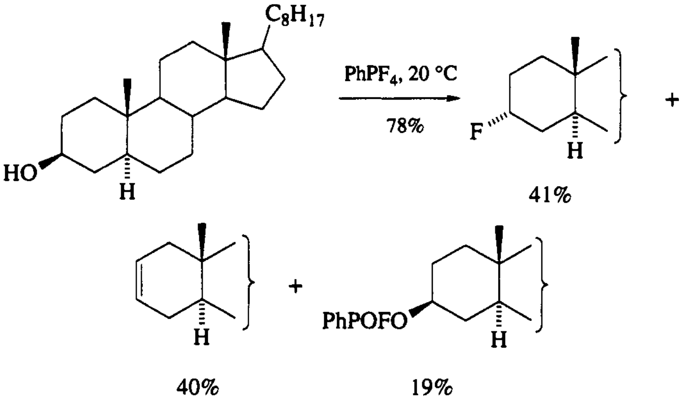
(39)

(40)



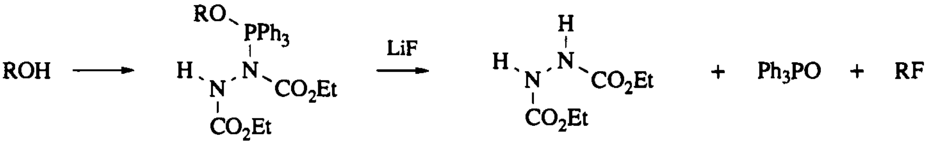
**Scheme 32**

$$\text{n-C}_8\text{H}_{17}\text{OH} \xrightarrow[78\%]{\text{Ph}_3\text{PF}_2,\ 150\ ^\circ\text{C}} \text{n-C}_8\text{H}_{17}\text{F} \tag{41}$$



(42)

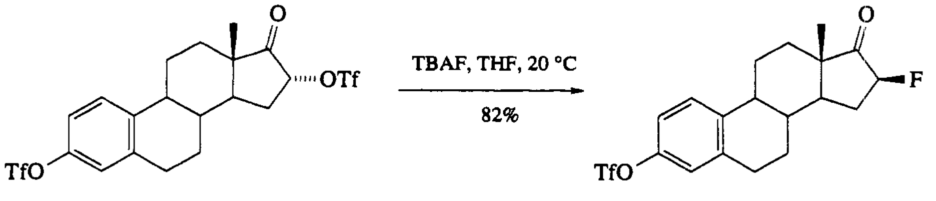
A preformed complex of diethyl azodicarboxylate/$Ph_3P$ activates primary and secondary alcohols sufficiently for $S_N2$-type reactions with LiF (Scheme 33).[42] This Mitsunobu procedure is a rare example of a reaction useful with all four halogens.



**Scheme 33**

### 1.7.5.2 Fluorination of Alkyl Alcohol Derivatives

The fluoride ion is only a weak nucleophile in water, due to high solvation. Aprotic solvents, however, do not solvate fluoride as readily. Accordingly fluoride is a strong nucleophile in aprotic solvents in the absence of water. Tetrabutylammonium fluoride (TBAF) is a commercial product, which transforms triflates to fluorides with inversion of configuration (equation 43).[118] Triflates react even with the commercial TBAF, although this is not free of water. Partial removal of water from TBAF results not only in a more potent source of nucleophilic fluoride but also in a more potent base; elimination may then become the dominant reaction.[119] If complete removal of water is attempted, the strong base properties cause *E*2 elimination, which decomposes the reagent itself (Scheme 34).[120] With metal fluorides like CsF the reagent itself is perfectly stable.

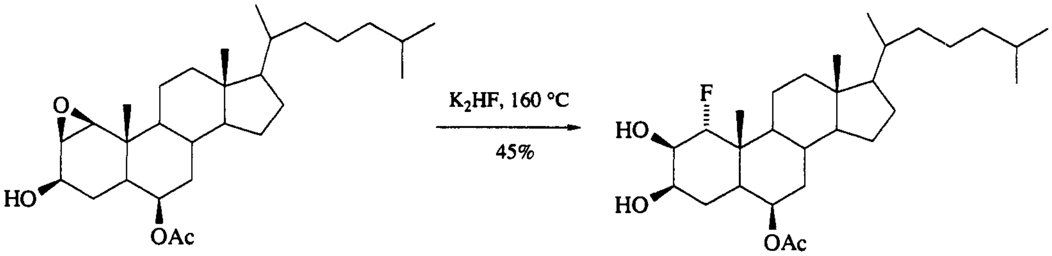


(43)

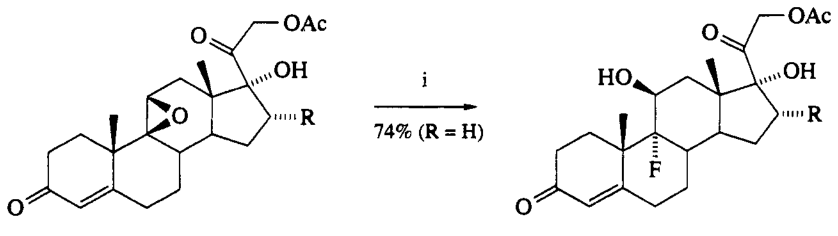
Scheme 34

### 1.7.5.3 Fluorination of Epoxides

Open chain ethers are not cleaved by HF or other fluoride sources. Epoxides, however, are easily opened by HF or $KHF_2$ to fluorohydrins. The reaction has been widely used in steroid chemistry (equation 44).[121] Dexamethasone is still a practical, important corticoid, which is synthesized on an industrial scale with the help of an epoxide-opening reaction (equation 45).[122,123] The low temperature needed for rigid steroidal epoxides and the high regio- and stereo-selectivity are remarkable. HF/pyridine is even more convenient for the opening of rigid epoxides. Side reactions often predominate with nonrigid, less reactive epoxides.[124]



(44)

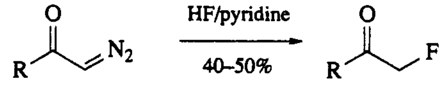


(45)

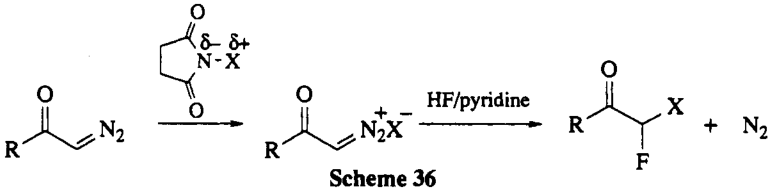
i, HF, $THF/CHCl_3$, –30 °C, 4 h (Dexamethasone: $\Delta^1$, R = Me)

### 1.7.5.4 Fluorination of Diazo Ketones

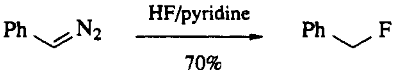
Diazo ketones react with HF/pyridine to give the corresponding fluoro ketones (Scheme 35).[108] Reactions in the presence of *N*-halosuccinimides result in the formation of geminally dihalogenated compounds. The mechanism involves initial attack by electrophilic halogen followed by nucleophilic displacement of nitrogen by fluoride ion (Scheme 36). Diazo alkanes give fluoro alkanes with HF/pyridine in good yields (equation 46).



Scheme 35



Scheme 36



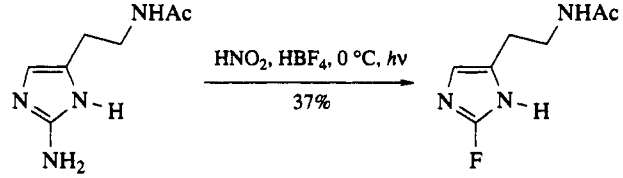
(46)

### 1.7.5.5 Fluorination of Diazonium Salts

Selective introduction of fluorine into an aromatic ring is often achieved by thermal decomposition of diazonium fluoroborates, which is called the Balz–Schiemann reaction (Scheme 37).[125,126] The scope of the reaction is wide and includes heterocyclic compounds (equation 47).[127] The $BF_4^-$ salts are unusually stable for diazonium salts and yields are usually high. In some cases, however, use of $PF_6^-$ or $SbF_6^-$ salts gives improved yields.[128]

$$ArN_2^+BF_4^- \xrightarrow{\Delta} ArF + N_2 + BF_3$$

Scheme 37

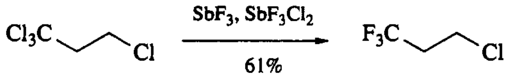


(47)

The mechanism involves a positively charged intermediate, which is attacked by $BF_4^-$ rather than fluoride. The decomposition follows a first-order law, so it is probably of $S_N1$ type.[129]

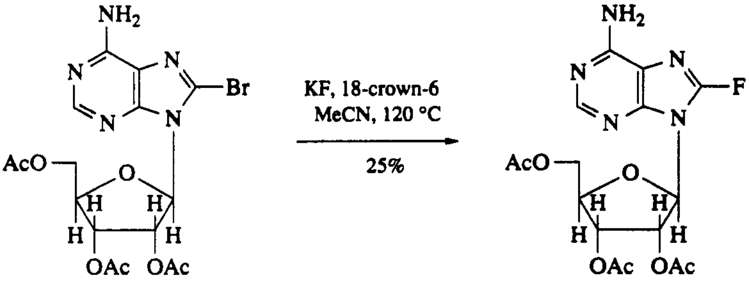
### 1.7.5.6 Other Fluorinations

The classical route to fluorinated organic compounds is the metathetical halogen–fluorine exchange. Polychloroalkanes are converted to polychlorofluoroalkanes with anhydrous HF. Reactions are carried out in autoclaves at temperatures of 50–150 °C in the presence of catalysts like antimony tri- or pentachloride. Chlorofluorocarbons are produced worldwide in large quantities by this method and used as refrigerants and foamers for plastics. For small scale preparations metal fluorides are more convenient to use. $SbF_3$ gives similar products as anhydrous HF and is activated by the addition of catalysts like chlorine, bromine or $SbCl_5$ (equation 48).[130] The replacement of halogens in polyhalogenated compounds becomes more difficult with increasing fluorination. The formation of perfluoro compounds by replacement of the last fluorine requires severe conditions.



(48)

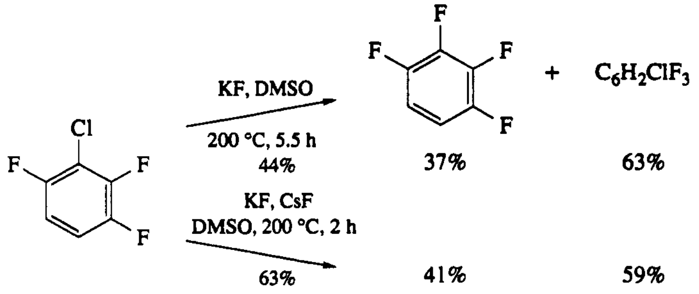
$SbF_3$ does not exchange single halogens at $sp^3$ or $sp^2$ carbon centers. A more general reagent for the metathetical reaction is KF. Even aromatic (equation 49)[117] or primary alkyl (equation 50)[131] halides are exchanged to fluorides if phase transfer catalysts are used.[132] The classical conditions for a similar reaction give lower yields (equation 51).[133] Addition of CsF to KF results in faster reactions with higher yields (equations 52 and 53).[134]



(49)

$$\text{n-C}_8\text{H}_{17}\text{Cl} \xrightarrow[82\%]{\text{aq. KF, }(\text{C}_{16}\text{H}_{33})\text{Bu}_3\text{PBr, 160 °C, 7 h}} \text{n-C}_8\text{H}_{17}\text{F} \qquad (50)$$

$$\text{n-C}_6\text{H}_{13}\text{Cl} \xrightarrow[54\%]{\text{KF, glycol, 180 °C}} \text{n-C}_6\text{H}_{13}\text{F} \qquad (51)$$



(52)

## 1.8.1 NITRILES

### 1.8.1.1 Introduction

Nitriles comprise one of the classical functional groups of organic chemistry. The present review deals with useful preparative methods for the synthesis of nitriles by displacement reactions. In view of the extensive current activity in this area, it is necessary to be selective rather than comprehensive. A series of outstanding review articles[1–6] will guarantee rapid acquaintance with the field and some complementary accounts,[7,8] not repeatedly cited, inform of recent developments.

### 1.8.1.2 By Replacement of a Halogen Substituent

#### *1.8.1.2.1 Alkyl halides*

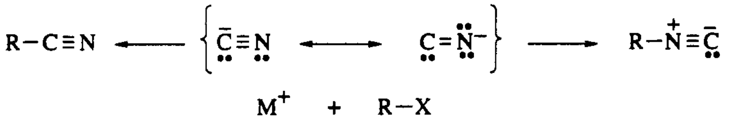
*(i) General remarks*

The transformation of alkyl halides with cyanides (equation 1) represents not only the 'classical' route to nitriles, but, if modified properly, is still of very great practical importance even today. A whole series of review articles[1–6] stress the scope and value of this reaction. Although the substituent 'R' may be varied to a large extent, the primary as well as the benzylic halides generally give higher yields than secondary and tertiary ones, as, with the latter, the formation of alkenes gains in importance. This side reaction as well as the undesired formation of alcohols and ethers, which sometimes takes place in aqueous media or with alcohols as solvent, is of course due to the basicity of the cyanide ion. Under deleterious conditions one may even observe carboxylic acids, which result from the hydrolysis of the nitriles.[2,9] Some of these undesired side reactions may be avoided by the use of CuCN instead of sodium or potassium cyanide.[2]

$$\mathrm{R{-}X} \ + \ \mathrm{MCN} \longrightarrow \mathrm{R{-}CN} \ + \ \mathrm{M{-}X} \qquad (1)$$

X = halogen

As cyanide ions operate as ambident nucleophiles, alkylation reactions may generate isonitriles as well as nitriles (equation 2). A whole range of parameters is responsible for the outcome of reactions of this type and their particular role together with special counter influences is not easily evaluated. There is a large and growing number of papers on this topic, but one can concentrate here on a few selected review articles.[10,11] Suffice it to say that Kornblum's seminal article[12] from 1955 is still of special importance in this field. Pearson's principle of soft and hard acids and bases (HSAB) proved to be particularly helpful in the interpretation of experimental results.[11,13,14]



$$\mathrm{R{-}C{\equiv}N} \longleftarrow \left\{ \overset{-}{\mathrm{C}}{\equiv}\mathrm{N} \longleftrightarrow \mathrm{C}{=}\mathrm{N}^{-} \right\} \longrightarrow \mathrm{R{-}}\overset{+}{\mathrm{N}}{\equiv}\overset{-}{\mathrm{C}} \qquad (2)$$
$$\mathrm{M}^{+} \ + \ \mathrm{R{-}X}$$

X = halogen

Of particular preparative value is the observation that ambident anion alkylations, by appropriate choice of reaction conditions, may be manipulated to operate preferentially in one direction. The results of Guillemard's classical work in this area have been reviewed by Kurtz.[2] Although most of the modern investigations do not deal in particular with the nitrile/isonitrile problem, the following rules can be summarized.

(i) Given kinetically controlled reactions, an $S_N1$-type transformation of alkyl halides with cyanide ions should favor the formation of isonitriles. In a charge-controlled reaction the ambident cyanide nucleophile will tend to attack the carbon of the alkyl halide with the more electronegative nitrogen, the center of greater charge density. With $S_N1$ substitutions there will also be a comparatively high positive charge density on the carbon atom of the alkyl halide, although this does not necessarily mean the existence of a discrete cationic intermediate. Even a partially charged carbon atom, according to Pearson's classifications, has to be considered a relatively hard electrophile and should therefore interact most easily with the nitrogen atom of the cyanide ion, which does represent the harder base in this combination,[13] to generate the isonitrile. In Section 1.8.2 the synthetic possibilities will be discussed in detail.

(ii) Accordingly $S_N2$ substitution conditions will favor the formation of nitriles. In an orbital-controlled transformation the less electronegative, but more nucleophilic carbon atom of the $CN^-$ ion will attack the alkyl halide in an $S_N2$-type reaction. The halide-substituted carbon of R—X (X = halogen) may be considered a soft electrophile, thus classifying the formation of nitriles as a soft–soft interaction. Primary halides should therefore be the best candidates for the formation of nitriles and Table 1 proves this for a large number of examples.

If a particular nitrile is being aimed at, there will be no possibility of changing the nature of R in order to promote an $S_N2$ process. Therefore it may be of interest that the nature of the transition state may also be influenced by other parameters. So, important consequences may be expected from changing the

leaving group. As the polarity of the bond between the leaving group and the carbon atom increases, as shown in equation (3), the likelihood of an $S_N1$ process occurring increases. Within certain limits even the countercation will be able to influence the $S_N1/S_N2$ ratio: with AgCN for instance (sometimes zinc cyanide, CuCN or HgCN have also been used) the initial formation of silver halides ionizes the alkyl halide to a large extent, thus imposing a comparatively high positive charge on the carbon atom. In the transition state there will be a higher positive charge at this center, which, by enhancing the $S_N1$ character, will favor the formation of isonitriles. On the other hand, alkali metal cyanides will be used, if the corresponding nitriles are required. A practical application resulting from these considerations is the optimized preparation of ethyl isocyanide from iodoethane and silver cyanide, as described in *Organic Synthesis*.[15]

$$\xrightarrow[\text{increasing } S_N1 \text{ character}]{X\ =\ I,\ Br,\ Cl,\ OSO_2R} \qquad (3)$$

It should be mentioned briefly that solvation phenomena should also influence the outcome in the case of ambident nucleophiles, at least to the extent to which these reagents are sensitive to solvent effects. With an ambident anion, which is not manipulated by countercations (formation of ion pairs), the more electronegative center should attack preferentially. The more this area is blocked by hydrogen bridges formed in protic solvents, or shielded by countercations, the more likely it is that the less electronegative end will react. If dipolar aprotic solvents are used, which can only solvate the cations, a preferential attack of the nonshielded more electronegative center is to be expected. It must be realized, however, that in substitution reactions employing cyanide ions, dipolar aprotic solvents have not been reported to enhance the formation of isonitriles.[16–18]

Assessing the relative importance of the various factors, which also has to include steric effects, is a complicated task. As already mentioned, nitrile formation in general is favored in these substitution reactions (equation 1), and as isonitriles are normally formed to only a very small extent, they can easily be removed by extraction with diluted mineral acids.

### (ii) Preparative possibilities

As will be shown, a whole range of variations and modifications is known for the reaction of alkyl halides with cyanide ions (equation 4). Without trying to cover every detail, an attempt will be made to mention the most important procedures and to give a few typical examples (see Tables 1 and 2). Despite the diversity of the reaction conditions, a general comparison of their synthetic importance is useful.

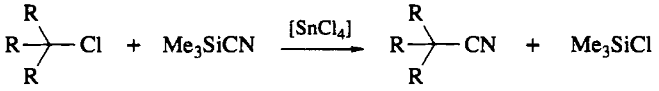
The transformation of alkyl halides into alkanenitriles with cyanide ions has frequently been carried out in protic solvents such as methanol or ethanol, sometimes with the addition of water or acetone, and often at elevated temperatures. Under these conditions reaction rates decrease in the order iodides, bromides, chlorides, as would be expected. Accordingly iodide ions have a catalytic effect and increase reaction rates.[2,4] The use of anhydrous ethylene glycol or di- and poly-ethylene glycols and their corresponding ethers allows the use of higher temperatures, which means better solubility of the alkali metal cyanides.[2,4,19] There is probably additional help from the extensive solvation of the countercations by some of these hydroxy polyethers. While for primary halides yields for nitriles range up to 90% (Table 1), they drop sharply with secondary and tertiary halides.[3]

Particularly good results have been reported (Table 1) with dipolar aprotic solvents like DMSO, DMF, formamide or HMPA,[3,4] which exclusively solvate cations and thus generate highly reactive 'naked' cyanide anions. As a consequence a remarkable increase in reaction rates is observed. The most impressive results were seen with DMSO. Under these conditions even alkyl bromides and chlorides are very useful starting materials and not only primary, but also secondary halides can give rise to high yields if there is not too much steric hindrance (Table 1). Tertiary halides even under these conditions are poor substrates. The cation also may, even if one focuses on alkali metal cyanides, sometimes have a strong influence on reaction rates. With sterically hindered halides for instance, NaCN seems to be superior to the potassium salt in DMSO.[3] Another modification is the use of LiCN in boiling THF; NaCN and KCN fail under these conditions. There has also been a very thorough investigation of the use of tetraalkylammonium cyanides and quite good results were obtained with the tetraethyl or tetrabutyl derivative.[21] Using these highly soluble cyanides, one can run the reaction not only in many polar solvents, *e.g.* acetonitrile, but also in comparatively nonpolar solvents such as $CH_2Cl_2$ and THF, or even benzene or toluene, and at high concentrations. Slowly reacting compounds will again be used in DMSO.[21] Even neopentyl bromide yields 55% of the corresponding nitrile, if treated with tetraethylammonium cyanide in acetonitrile.

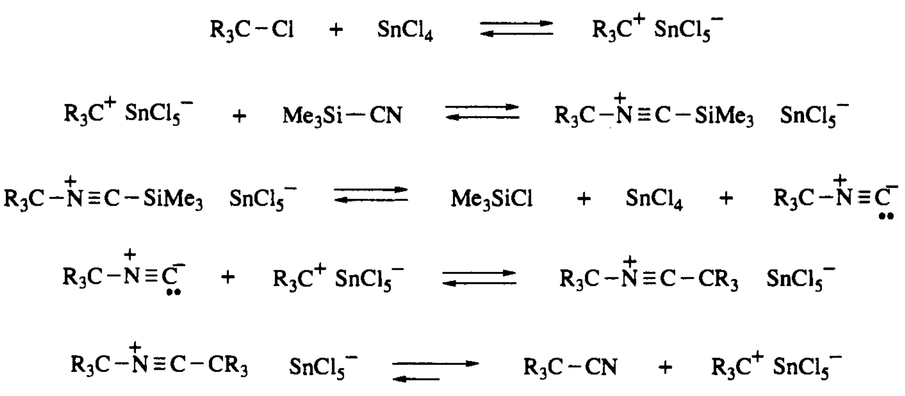
Phase transfer catalysis and the use of crown ethers are also of particular advantage in alkanenitrile synthesis (Table 1). Usually quaternary ammonium and phosphonium salts serve quite well as catalysts.[3] Another modification is represented by the use of a solid catalyst, which is insoluble in the two-phase system, for instance alumina or anion-exchange resins (triphase catalysis).[3,7] Crown ethers again capture the cations and generate 'naked' cyanide ions in fairly nonpolar solvents, leading to exceptionally mild reaction conditions.

The use of 'reversed micelles' for the preparation of nitriles is a particularly interesting modern development.[22] Some examples can be found in Table 1.

As discussed above, the classical procedures for the transformation of alkyl halides fail with tertiary derivatives. Trimethylsilyl cyanide (TMS-CN)[23] recently turned out to be the reagent of choice in this case. It may easily be obtained from trimethylchlorosilane,[24-28] but is also available commercially. In this way various *t*-alkyl and cycloalkyl chlorides can be converted to the corresponding nitriles in the presence of a catalytic amount of $SnCl_4$ at room temperature and in solvents such as $CH_2Cl_2$ (equation 5). The yields range between 64 and 80% (Table 1). A sharp drop in yields is observed with educts, however, which have an electron-withdrawing group (EWG) in the neighborhood of the reaction center, as was noticed with 1,1,1,2-tetrachloro-2-methylpropane (yield < 5%) or methyl 2-chloro-2-methylpropanoate (<5%). Isonitriles are not observed in the course of the reaction, although they may play a crucial role in the reaction sequence. A number of observations led to the following mechanism (Scheme 1).[23]



$$R_3C-Cl + Me_3SiCN \xrightarrow{[SnCl_4]} R_3C-CN + Me_3SiCl \qquad (5)$$



$$R_3C-Cl + SnCl_4 \rightleftharpoons R_3C^+\ SnCl_5^-$$

$$R_3C^+\ SnCl_5^- + Me_3Si-CN \rightleftharpoons R_3C-\overset{+}{N}\equiv C-SiMe_3\ \ SnCl_5^-$$

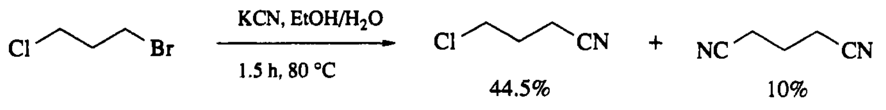
$$R_3C-\overset{+}{N}\equiv C-SiMe_3\ \ SnCl_5^- \rightleftharpoons Me_3SiCl + SnCl_4 + R_3C-\overset{+}{N}\equiv \underset{\bullet\bullet}{C^-}$$

$$R_3C-\overset{+}{N}\equiv \underset{\bullet\bullet}{C^-} + R_3C^+\ SnCl_5^- \rightleftharpoons R_3C-\overset{+}{N}\equiv C-CR_3\ \ SnCl_5^-$$

$$R_3C-\overset{+}{N}\equiv C-CR_3\ \ SnCl_5^- \rightleftharpoons R_3C-CN + R_3C^+\ SnCl_5^-$$

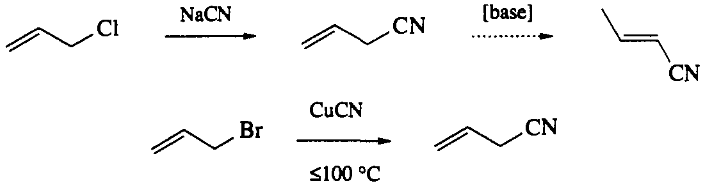
**Scheme 1**

By using displacement reactions even nitriles that carry a number of functional groups may be prepared. Dinitriles may also be obtained by this method; in the case of ω-chloroalkyl bromides, the bromine atom is exchanged preferentially (equation 6).[2] Dichloro compounds may also be converted into the corresponding dinitriles. This is done mainly in dipolar aprotic solvents such as DMSO or with the help of phase transfer catalysis or crown ethers (Table 2).[3] Generally, the generation of dinitriles does not create any special problems. It should be mentioned that even in γ-halocarboxylic acids a smooth halogen/nitrile exchange is possible.[2]

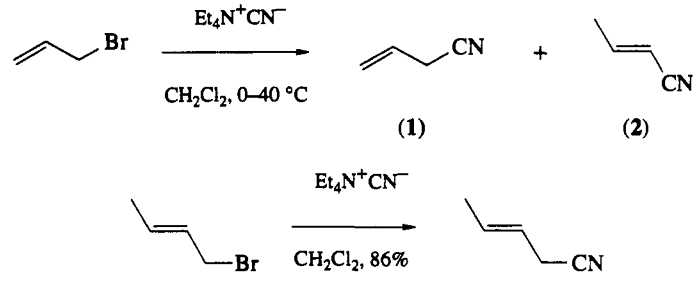


(6)

β,γ-Unsaturated alkanenitriles may often be generated quite easily from allyl halides and cyanide ions. Unfortunately, the preparation of pure compounds suffers sometimes from the formation of rearrangement products (Scheme 2).[2,4] In this case the use of CuCN is expected to be of advantage.[2,4] An 80–84% yield of allyl cyanide may be obtained on treatment of neat allylic bromide with CuCN (Scheme 2).[33] A quite remarkable influence of the reaction conditions is observed, for instance, in the reaction of tetraethylammonium cyanide with allylic bromide.[21] If the cyanide, dissolved in $CH_2Cl_2$, is slowly added to a cold solution of allylic bromide in the same solvent, the main product, allylic cyanide (**1**), will dominate in a 15:1 ratio against crotononitrile (**2**), while the addition of allylic bromide to a boiling solution of the ammonium cyanide in methylene chloride provides 70% (**2**), which is accompanied by only 8% of compound (**1**). On the other hand, 1-bromo-2-butene gives rise to 1-cyano-2-butene exclusively, independent of reaction conditions (Scheme 3).[21] A great number of patents on this topic have been reviewed by Kurtz.[2]



**Scheme 2**



**Scheme 3**

α-Cyano ethers may be obtained from the corresponding halogen precursors (which are quickly destroyed in aqueous or alcoholic solution) with NaCN in DMF or DMSO.[4] Earlier papers recommend the use of CuCN, sometimes without any solvents.[2,4] Good results are reported again for the transformation of α-chloro ethers with tetraethylammonium cyanide in $CH_2Cl_2$,[23] or with TMS-CN/$SnCl_4$ (Scheme 4).[23] In the carbohydrate series nitriles are often prepared by reaction of the corresponding bromo derivative with $Hg(CN)_2$. No special care has to be taken in the formation of alkoxynitriles, where the ether moiety is separated from the nitrile group by at least two carbon atoms.[2]

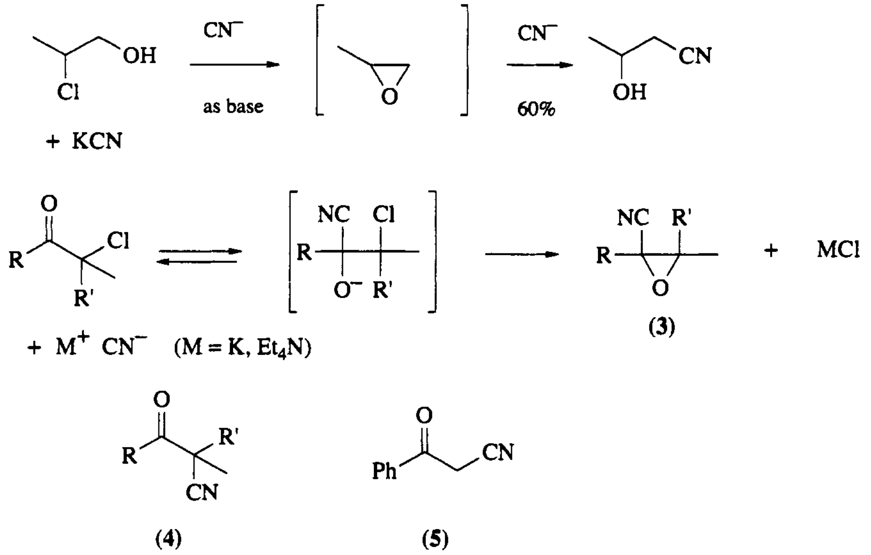
**Scheme 4**

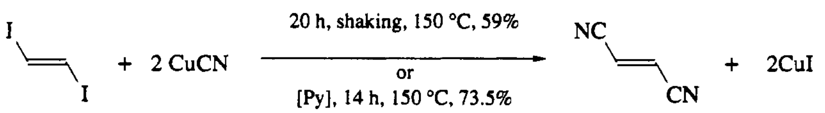
In the reaction of 2-hydroxyalkyl halides with cyanide ions the intermediate formation of oxiranes can give rise to rearrangement products. Epoxides may also be encountered if $CN^-$ ions are reacted with α-halo ketones (Scheme 5).[2,3] On heating with quaternary ammonium halides in acetonitrile or DMSO at 80–130 °C these cyanooxiranes (**3**) are converted into 2-cyano ketones (**4**).[21] Phenacyl bromide, in contrast, gives rise to 3-oxo-3-phenylpropionitrile (**5**) on treatment with cyanide ions.[21] Not much is known about the reaction of the corresponding α-halo sulfides with cyanide;[34] ethylthioacetonitrile was obtained from the chloro sulfide by treatment with $Hg(CN)_2$.[35]



**Scheme 5**

### 1.8.1.2.2 Vinyl and aryl halides

The low reactivity of vinyl halides in nucleophilic displacement reactions is well known. For preparative procedures the use of CuCN, sometimes in the presence of bases like pyridine, at temperatures higher than 200 °C (closed vessel) is recommended.[2,4] This technique may be used to prepare maleonitrile and fumaronitrile from *cis*- and *trans*-1,2-diiodoethylene (equation 7).[2,4]

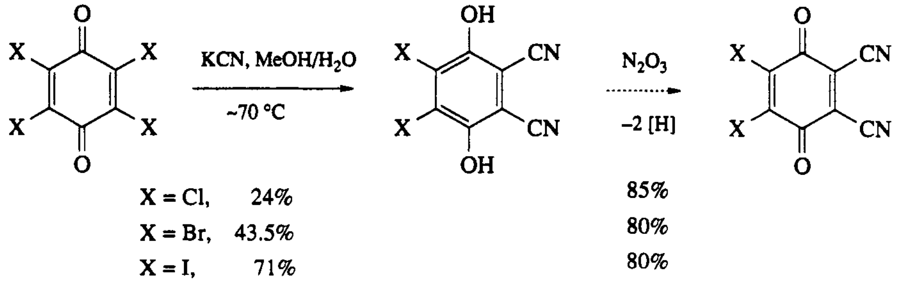


(7)

The reaction of haloquinones with cyanide ions in aqueous ethanol, which yields cyanohydroquinones (Scheme 6),[2] formally represents the same type of reaction. The synthesis of vinyl cyanides from the corresponding halides with KCN in the presence of crown ethers and a $Pd^0$ catalyst can be run under much milder conditions (60–100 °C) in benzene or pyridine as the solvent.[3] The transformations turn out to be nearly stereospecific. Comparable results are obtained at 50 °C with a $Ni^0$ catalyst, prepared *in situ* from bis(triphenylphosphine)bromonickel(II) on treatment with zinc and triphenylphosphine in DMF or DMSO. The stereospecificity is only slightly inferior to the $Pd^0$ catalyst.[3] With both systems yields of more than 90% can be reached. A series of examples is given in a table by Grundmann.[3]

Although the preparation of aryl cyanides from the corresponding halogen compounds is described by the very simple equation (8), the process does not correspond to a simple aromatic substitution reaction. In a series of comprehensive articles[2,3,8,36] various aspects of this transformation are discussed. An excellent review, written by Ellis and Romney-Alexander,[36] should be mentioned in particular, as it provides the literature leading into the modern status of the field.

As a 'classical' technique for the synthesis of aromatic cyanides treatment of the corresponding halides with CuCN has to be cited (Rosenmund–von Braun reaction).[1–4] It is carried out at 150–250 °C, either without any solvent at all, or using pyridine or quinoline, which also operate as complexing agents for the CuCN. Other heavy metal cyanides or hexacyanoferrates have been used in principle, but their



Scheme 6

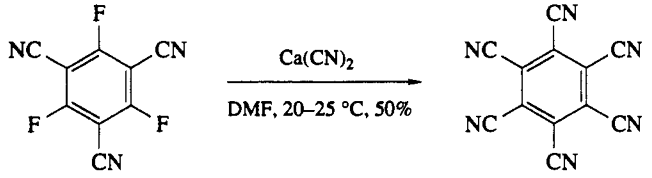
$$\mathrm{Ar{-}X} + \mathrm{CN^-} \xrightarrow{\Delta} \mathrm{Ar{-}CN} + \mathrm{X^-} \qquad (8)$$

X = halogen

practical importance seems to be low. In recent years DMF, HMPA, NMP or tetramethylurea proved to be very useful solvents. As the reactions with these dipolar aprotic solvents can be run using comparatively mild conditions, it has also been possible to apply this transformation to quite sensitive and nonactivated educts.[3,4,36]

Although aryl iodides represent the most reactive substrates, a very large number of reactions have been run with the bromides, as these are more easily available and still offer satisfactory reactivity. From chloroaryl iodides the corresponding chloronitriles may be obtained with remarkable selectivity. Many heteroaromatic halogen compounds have been transformed into the corresponding nitriles in an analogous manner.[3,4,36]

The substitution pattern of the aromatic ring tends to influence the reaction rates, but the relationship is not very clear cut. Chloro ligands in the 2-position as well as nitro and carboxy groups in the 2- or 4-position seem to increase the reaction rates. There are additional successful transformations with the following substituents: primary amino, tertiary amino, alkoxy, alkylthio, hydroxy, alkyl, formyl, acyl, carboxy, alkoxycarbonyl and nitro groups. Polyhalogenated educts give rise to polynitriles.[8] Starting from 2,4,6-trifluorotricyanobenzene even hexacyanobenzene may be obtained (equation 9).[37]



(9)

For work-up of the reaction mixtures, reagents which destroy the nitrile–copper cyanide complexes, for instance $Fe^{III}$/HCl (oxidation of $Cu^{I}$ to $Cu^{II}$, followed by extraction of the nitrile), ethylenediamine (complexation of Cu ions) or an excess of aqueous NaCN (formation of the soluble $NaCu(CN)_2$), proved to be particularly useful.[38] With appropriate *ortho* substituents, such as carboxy groups, cyclization reactions may be observed under the reaction conditions.[4] If treated at higher temperatures with CuCN, *o*-dihalides often provide phthalocyanines.

The mechanism of of these substitution processes, in spite of numerous investigations, is not completely (or not for all variants) solved in detail. As reaction conditions differ very much, one may not even expect a simple homogeneous mechanism. The crucial role of Cu complexes is, however, widely accepted. A very thorough discussion of all aspects can be found in some comprehensive accounts.[36,39]

An excellent overview with numerous tables, providing details on the reaction conditions and disclosing scope and limitations of all transformations of aromatic halogen compounds with CuCN, is provided by Grundmann[3] as well as Ellis and Romney-Alexander[36] (more than 200 examples, some of them with preparative variations). They list various reaction conditions, so that it is not necessary to discuss individual examples here.

Under remarkably mild conditions aromatic cyanides can be prepared from halogen compounds with alkali metal cyanides in the presence of transition metal complexes.[3,36] Complexes of palladium and nickel are particularly useful, for instance tetrakis(triphenylphosphine)palladium(0) (**6**), tris(triphenylphosphine)nickel(0) (**7**) or *trans*-dichlorobis(triphenylphosphine)nickel(II) (**8**; Scheme 7).

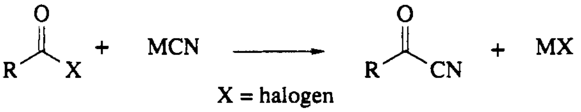
| $(Ph_3P)_4Pd$ | $(Ph_3P)_4Ni$ | $Cl_2Ni(PPh_3)_2$ |
|---|---|---|
| **(6)** | **(7)** | **(8)** |

**Scheme 7**

Various cobalt complexes have also been used. While the use of these complexes is more expensive and needs more demanding reaction conditions (oxygen must be strictly excluded), the transformations can be done at comparatively low reaction temperatures. Very often high yields will be obtained at 50–60 °C, and in some cases reactions have even been run at 30 °C. Yields of up to 80–90% are not unusual. The addition of crown ethers proved to be quite helpful in various cases. Instead of alkali metal cyanides, acetone cyanohydrin can also be used.[36] A discussion of relevant mechanistic aspects can be found in eview articles.[3,36,40] Again the aromatic ring may carry various substituents, although *ortho* - ligands tend to give rise to lower yields.[36] Another drawback seems to be the interaction of nitro groups with the catalysts. Depending on the stability of the catalytic system under investigation, one may in principle decide on various polar or nonpolar solvents and details on this matter can again be found from reaction tables provided in the literature.[36] The reaction of aryl iodides with TMS-CN/$(Ph_3P)_4Pd$ in boiling triethylamine was studied recently.[41]

### *1.8.1.2.3 Acyl halides*

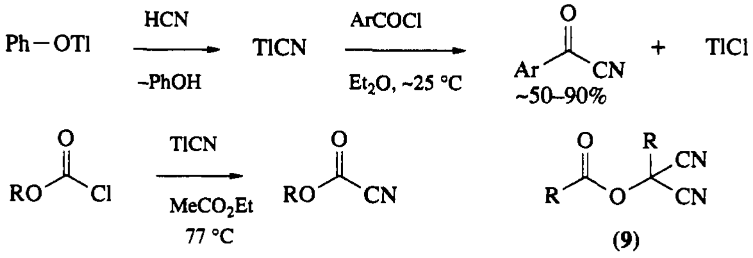
The preparation of benzoyl cyanide on distillation of benzoyl chloride and HgCN, which was reported by Liebig and Wöhler in 1832,[42] has to be regarded as a cornerstone in nitrile chemistry, as this documents the first synthesis of an organic nitrile. Today numerous methods for the preparation of these important acylnitriles are known (equation 10). A number of review articles[2,3,7,43–45] provide quick access to the original papers, the very broad patent literature included.



(10)

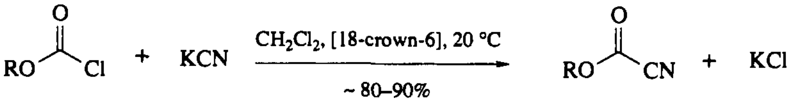
The most favored technique for quite a while was the transformation of the, compared to acyl chlorides, much more reactive acyl bromides with AgCN or CuCN at elevated temperatures.[2,3,7,45] A whole range of phosphorus compounds may be used as catalyst.[4] Dry alkali metal cyanides were for some time considered to be useless, probably because of their poor solubility in solvents like benzene. Aqueous solvents and alcohols are of course useless, as they react very quickly with the starting material as well as with the product. At this stage the particular sensitivity of acylnitriles to protic solvents and basic or acidic reagents should be mentioned.[2,4] Recently very good results were reported in many cases from the transformation of acid chlorides and CuCN in acetonitrile, which may also operate as a complexing ligand.[3,45] In another modification, aroyl chlorides are treated with CuCN in the presence of LiI in solvents such as diethyl ether.[46] An interesting technique makes use of the reaction of the (difficult to obtain) TlCN with an aroyl chloride in ether or ethyl acetate at room temperature (Scheme 8); high yields of aroyl cyanides are described.[3,45] One cannot apply this method, however, to the preparation of the corresponding aliphatic acyl cyanides, as dimers such as (**9**) are mainly formed under the reaction conditions. If this dimerization is blocked by steric hindrance, it may be possible to isolate the desired acylnitriles. The preparation of 3,3-dimethyl-2-oxobutyronitrile, which was obtained in 45% yield, provides an example of this method.[3] Even cyanoformates can be prepared from chloroformates and TlCN in acceptable yields (Scheme 8).[3] An often quite useful modification, which permits the synthesis of sensitive acyl cyanides, uses the reaction of acyl iodides (which can be generated *in situ* from acid chlorides on treatment with NaI in acetonitrile) with CuCN.[3,47] Although the corresponding isonitriles could well be intermediates, this question is not dealt with by the author[47] (but see also ref. 45). In $CH_2Cl_2$ or acetonitrile good yields are obtained under mild conditions. In the same manner α,β-unsaturated acyl halides and phenyl iodoformate can be transformed into the corresponding nitriles.

Now even alkali metal cyanides are used for the preparation of acylnitriles. The transformation of chloroformates with KCN using phase transfer catalysis can be achieved under very mild conditions. The yields, however, are frequently much lower than those from the TlCN technique.[3,45,48] Probably these deficits may be compensated for by the very convenient operations under phase transfer conditions ($Bu_4N^+Br^-$ in water/$CH_2Cl_2$). The reaction of numerous chloroformates with KCN/18-crown-6 in $CH_2Cl_2$ (equation 11) is reported to give excellent yields.[3,45,49]



R = alkyl

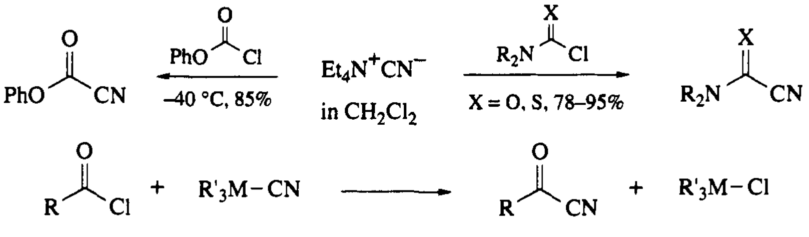
**Scheme 8**



(11)

The recent application of sonochemistry to the reaction of aroyl chlorides with KCN in acetonitrile is very interesting.[3] Aromatic acyl cyanides could also be prepared by reaction of aroyl chlorides with KCN impregnated onto XAD resins.[50] A number of patents describe the results of the two-phase interactions of alkali metal cyanides with a solution of acyl halides or anhydrides in aprotic organic solvents, which in general run in the presence of Cu$^I$ salts.[45]

Due to its excellent solubility in $CH_2Cl_2$, triethylammonium cyanide also serves extremely well in this reaction. The transformation of phenyl chloroformate and (thio)carbamoyl chlorides yields the corresponding nitriles (Scheme 9).[3,21,45] Alkyl chloroformates fail under these conditions as a result of decarboxylation. Trimethylsilyl cyanide (TMS-CN) has also proved to be a very useful reagent for the preparation of acyl cyanides (Scheme 9)[3,45] but see also ref. 47b. The TMS-Cl formed in the process (Scheme 9) is said to be a catalyst in this transformation. The reaction may also be catalyzed by small amounts of other Lewis acids such as $ZnI_2$ or, particularly for aroyl halides, $SnCl_4$. Unsaturated as well as haloalkanoyl chlorides or dicarboxylic acid dichlorides may be transformed in a similar fashion with very satisfactory results. It has to be mentioned, however, that highly reactive or enolizing acylnitriles may suffer from subsequent transformations.[3] In a further modification acylnitriles can also be prepared by reaction of various acid chlorides with cyanotributylstannane,[3,45] although primary and secondary acyl chlorides give rise to acyloxymalodinitriles (**9**).



R'$_3$M = Me$_3$Si , Bu$_3$Sn

**Scheme 9**

### 1.8.1.3 Exchange of Oxygen or Sulfur Functionality

The formation of alkanenitriles from alcohols and HCN is of no interest for laboratory preparations. However, a large number of publications, particularly patents, have appeared, which deal with technical applications of this procedure. A few review articles[2–4] serve very well as introductions to this field. Under particularly mild conditions allyl and propargyl alcohols can be transformed into the corresponding nitriles with hydrogen halides in the presence of Cu$^I$ salts.[2,4] The possibility of generating nitriles from alcohols *via* the analogous halides needs no further treatment at this stage.

An attractive procedure for the direct transformation of alcohols into nitriles operates with TMS-CN, generated *in situ* from TMS-Cl and NaCN with catalytic amounts of NaI.[51] The reaction (Scheme 10) is run in DMF/acetonitrile at about 60 °C and leads to good or even excellent yields with primary, secondary and also tertiary alcohols. With 3-β-cholestanol 85% of the nitrile (+ 6% cholest-2-ene) is formed with inversion.[51] Decisive, mechanistically relevant intermediates could be the nitrilium ion (**10**) as well as the oxonium ion (**11**; Scheme 10).[51] The preparation of nitriles from alkanols with KCN, triphenylphosphine and $CX_4$ (X = halogen) in the presence of crown ethers at room temperature (Scheme 11) is restricted to primary alcohols.[52] A second version (Scheme 11), which operates on primary and secondary alcohols, particularly in the carbohydrate series, makes use of triphenylphosphine, tetrachloromethane and DMSO at 90 °C under anhydrous conditions.[3] In the conversion of *o*- and *p*-hydroxybenzyl alcohols to the corresponding arylacetonitriles (NaCN, DMF, 110 °C) quinone methides are discussed as intermediates.[3]

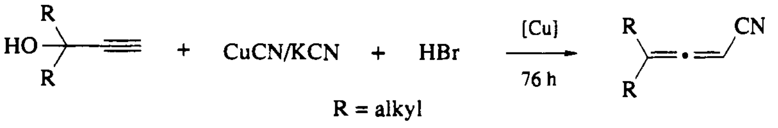
**Scheme 11**

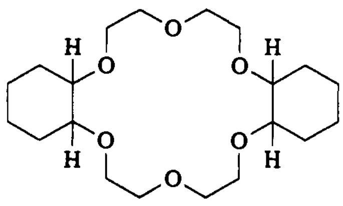
One should briefly mention the preparation of cyanoallenes from substituted 2-propynols, KCN and HBr in the presence of CuCN and copper (equation 12).[3] For a mechanistic discussion see ref. 53. In another route to cyanoallenes, the corresponding halides are first prepared from the alcohol and then treated with CuCN.[3]



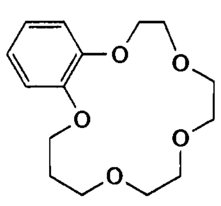
(12)

Various sulfuric and phosphoric acid esters have sometimes been used instead of alcohols as starting materials for the preparation of nitriles.[2,4] Of more general importance are sulfonates, particularly from methane- or *p*-toluene-sulfonic acid, which react in an $S_N2$-type substitution with cyanide ions. The most common starting materials are, as described in Section 1.8.1.2.1, alkyl halides, and if their preparation creates problems, the use of sulfonates may be advantageous.[3] The addition of crown ethers or the application of 'classical' phase transfer conditions may enhance the efficiency of this transformation.[51] The reaction of *n*-octyl methanesulfonate with a saturated aqueous KCN solution, in the presence of crown ether (**12**) at 100 °C, which gives rise to an 80% yield of the corresponding nitrile (Scheme 12), may serve as an example.[54] For the reaction of *n*-octyl bromide with NaCN and crown ether (**13**) for 24 h at 100 °C, a complete failure is reported.[54] The corresponding sulfonate, however, gave rise to 1-cyanooctane on treatment with LiCN in boiling THF.[20] According to literature reports,[3] sulfonic acid aryl and benzyl esters are not converted to nitriles under mild conditions. Carboxylic esters are not useful starting materials for the preparation of nitriles.[2,3] In contrast to this, γ-lactones give rise to the salts of γ-cyanocarboxylic acids without problems. Following a 'classical' procedure,[2] KCN is used without any solvent at 180–200 °C (equation 13). In spite of these forcing conditions, yields tend to be high.[2] There seems to be a possibility for milder reaction conditions by using DMSO as the solvent.[3]

$$\text{n-C}_8\text{H}_{17}-\text{OSO}_2\text{Me} \quad + \quad \text{KCN} \xrightarrow{\text{H}_2\text{O/[(12)]}} \text{n-C}_8\text{H}_{17}\text{CN} \quad + \quad \text{MeSO}_3^-\ \text{K}^+$$

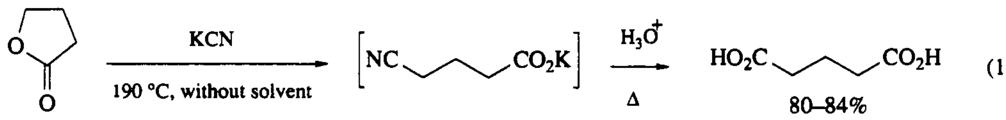


**(12)**

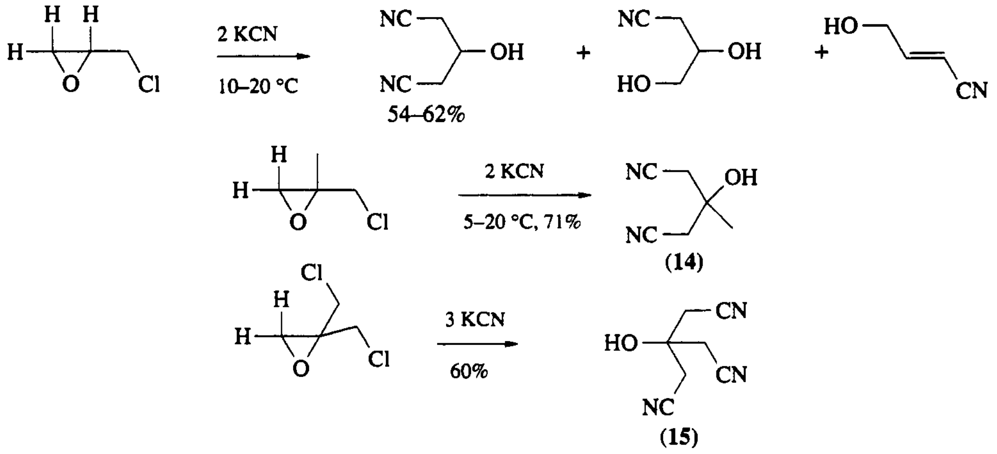


**(13)**

**Scheme 12**



The generation of 3-hydroxypropionitrile from ethylene oxide and HCN in a closed vessel was described in 1878.[55] As the reactivity of epoxides exceeds that of acyclic ethers considerably, oxiranes do represent useful starting materials for hydroxynitriles and their derivatives.[2] For laboratory preparations, the use of alkali metal cyanides (Scheme 13)[56,57] instead of HCN will be more convenient.[3,4] The syntheses of (**14**) and (**15**) (Scheme 13)[57] were accomplished in a buffered ($MgSO_4$) aqueous solution at about pH 9.5. The intermediate formation of epoxides on treatment of 2-halo alcohols with $CN^-$ ions has already been mentioned in Section 1.8.1.2.1.ii.



**Scheme 13**

For the synthesis of *trans*-β-cyanohydroxy steroids from the corresponding epoxides treatment with HCN/triethyl aluminum or with diethyl aluminum cyanide proved to be particularly useful.[3]

Recently the transformation of oxiranes with TMS-CN in the presence of Lewis acids, which actually play a major role in this sequence, was investigated in detail. A few examples (Scheme 14)[58,59] were chosen to illustrate the topic.[3]

The same reaction products are obtained from epoxides and TMS-CN in the presence of aluminum alkoxides,[60] samarium, cerium or lanthanum chlorides[61] as well as titanium tetraisopropanoate,[62,63] which may all be considered comparatively 'hard' Lewis acids. On the other hand various groups demonstrated[60,64,65] that 'softer' Lewis acids like zinc, tin and palladium dichloride may give rise to isocyanides (Scheme 15).

The exchange of alkoxy groups for the cyanide function can also be achieved in acetals (cyclic types like dioxolanes and 1,3-dioxane derivatives included), *S,N*-acetals and ortho esters with the combination of TMS-CN/Lewis acids,[3,67–69] or under neutral conditions with transition metal salts as catalysts (Scheme 16).[70] Furanose derivatives may be treated with TMS-CN in a similar way.[3,67,68]

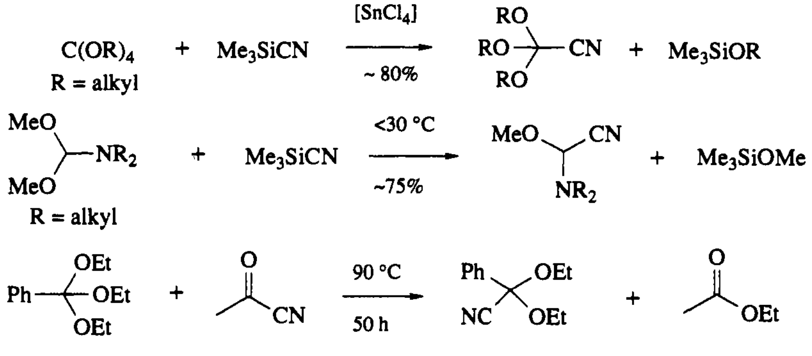
Orthocarbonates and their analogs do exchange just one alkoxy group with TMS-CN/$SnCl_4$ (Scheme 17). In earlier papers even the direct reaction with HCN and $ZnCl_2$ at room temperature was reported to give (after several days or even some weeks) high yields.[2,4] Treatment with acetyl cyanide (Scheme 17) represents another possibility for transforming orthoesters into bisalkoxynitriles.[71]



**Scheme 17**

An elegant procedure for generating α-cyano ethers from acyclic or cyclic acetals and ketals is their reaction with *t*-alkyl isocyanides in the presence of an equimolar amount of $TiCl_4$ (Scheme 18).[3,72] The exchange of alkoxy groups against cyanide functions proved to be very important for the preparation of cyanoquinones.[73]

**Scheme 18**

As with oxiranes, ring opening with TMS-CN/$AlCl_3$ can also be carried out with thiiranes.[74] Dialkylaminotrialkylstannanes react with episulfides without anyLewis acid catalysis.[74] For the synthesis of α-cyano sulfides from thioacetals or thioketals with TMS-CN (Scheme 19), $SnCl_4$ proved to be the best catalyst.[34] For the mechanistic interpretation the authors favor the isonitrile (**16**) as a key intermediate. An additional technique for preparing alkylthionitriles uses $Hg(CN)_2$ in the presence of $I_2$, thus reaching yields of up to 80%.[75]

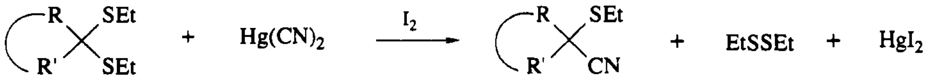
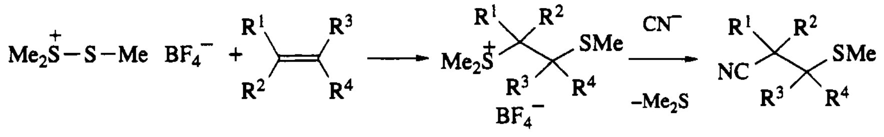


**Scheme 19**

The synthesis of α-methylthionitriles in high yield by 'cyanosulfenylation', *i.e.* addition of dimethyl(methylthio)sulfonium tetrafluoroborate to alkenes, followed by reaction with a CN donator, *e.g.* alkali metal cyanide/$HBF_4$ or TMS-CN (equation 15), was recently described by Trost.[76]



(15)

Sulfoxides may also be used for the preparation of nitriles: alkoxymethyl methyl sulfide, easily obtained from DMSO/acetic anhydride and primary alcohols, gives rise to the corresponding sulfoxides on treatment with MCPBA. By reaction with TMS-CN and $ZnI_2$, 2-alkoxyacetonitriles in good to excellent yields were obtained (Scheme 20).[77]

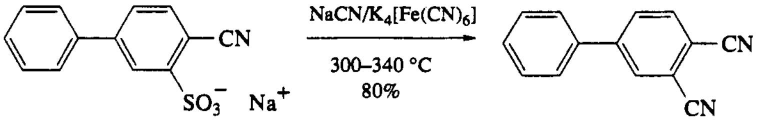
The thermal reaction between sulfonates and alkali metal cyanides (equation 16) or potassium hexacyanoferrate is more of historical value.[2,4] The finely powdered, dry and thoroughly mixed starting materials (equation 17) are heated up to 400 °C. For more efficient heat exchange the addition of mineral oil, sand, iron turnings or iron oxide is recommended. In spite of the quite forcing reaction conditions, yields of up to 80% are given in certain cases.[2]

$$ArSO_3M + MCN \xrightarrow{\Delta} Ar-CN + M_2SO_3 \qquad (16)$$



(17)

## 1.8.1.4 Exchange of Other Nitrogen Functionality

A quite important process for the preparation of aromatic nitriles is certainly the substitution of diazo groups by a cyanide function (equation 18). Following this route, the nitro or a primary amino group is, in principle, replaced by a CN ligand. The most important procedures are summarized in review articles[2,4] and in some shorter accounts.[78]

$$Ar-\overset{+}{N_2}\ X^- + CN^- \xrightarrow[\Delta,\ -N_2]{[CuCN]} Ar-CN \qquad (18)$$

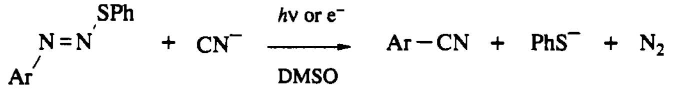
The first examples reported by Sandmeyer date back to 1884. The many various preparative procedures differ mainly in the type and the preparation of the copper–cyanide complex which is used.[2,4] In the 'Gattermann procedure' KCN in the presence of Cu powder is used. Generally one tries to avoid the formation of HCN on the addition of alkali metal cyanide to the acidic medium by neutralizing the diazonium salt solution in advance with sodium or barium carbonate. Cyanogen, which is formed from $CN^-$ ions on treatment with $Cu^{II}$ salts, is also a harmful by-product. In this case the addition of sodium hydrogen sulfite (equation 19) proved to be of great value.

$$2\,CuSO_4 + 2\,CN^- + HSO_3^- + H_2O \longrightarrow 2\,CuCN + 3\,HSO_4^- \qquad (19)$$

Better yields were often also obtained by use of the complex copper salt (**17**), prepared *in situ* from KCN and $CuSO_4$ in the presence of $NH_3$ (equation 20). In a thorough investigation Japanese workers[79] recently treated a series of aromatic amines with sodium nitrite in a mixture of polyethylene glycol and $CH_2Cl_2$ with HCl in a little water at 0 °C. After addition of the crystalline complex salt (**17**) the corresponding arenenitriles were obtained in high yield.

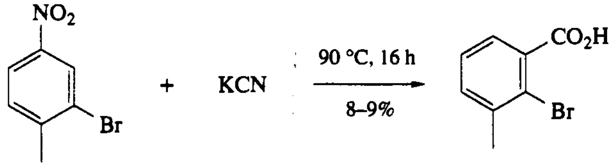
$$\mathrm{CuSO_4} + 4\,\mathrm{KCN} + \mathrm{NH_3} \longrightarrow \underset{(\mathbf{17})}{\mathrm{K_2[Cu(NH_3)(CN)_4]}} + \mathrm{K_2SO_4} \qquad (20)$$

The preparation of aromatic nitriles by an $S_{RN}1$ process was described recently.[80] Suitably substituted diazo sulfides, either isolated or only generated *in situ*, reacted with tetrabutylammonium cyanide under photon or electron stimulation (equation 21), leading to aryl cyanides with yields that are comparable with those of the Sandmeyer reaction. Bromo- and chloro-substituted aryl diazo sulfides afforded the corresponding dinitriles in high yields.



$$\mathrm{Ar{-}N{=}N{-}SPh} + \mathrm{CN^-} \xrightarrow[\text{DMSO}]{h\nu \text{ or } e^-} \mathrm{Ar{-}CN} + \mathrm{PhS^-} + \mathrm{N_2} \qquad (21)$$

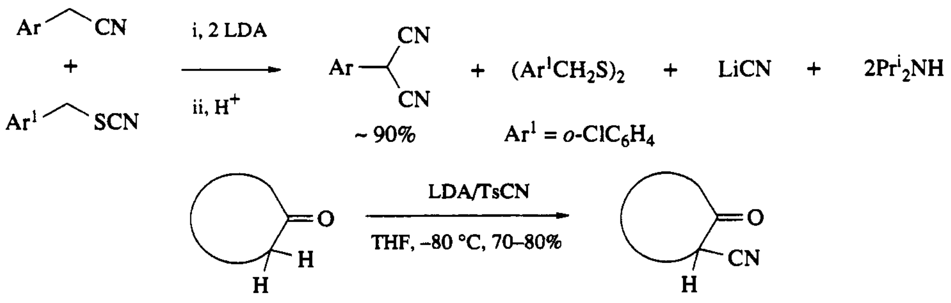
The thermally triggered transformation of aromatic nitro halides with KCN is known as the 'von Richter rearrangement'.[3,4,81] The process is illustrated in equation (22). In principle the nitro group is replaced by a cyano group by *cine* substitution, and a carboxylic acid is isolated, but with the carboxy group taking the *ortho* position to the former nitro substituent. The carboxy function is not formed by simple hydrolysis of the nitrile, as was believed for quite a period of time. A number of authors contributed to a better understanding of the reaction mechanism;[81–83] the details of the rearrangement, which involves heterocyclic intermediates, cannot be covered here. The yield of this reaction is generally rather low.



(22)

### 1.8.1.5 Exchange of a Hydrogen

The preparation of nitriles by (formal) exchange of a proton in alkyl-substituted aromatic and heteroaromatic systems, activated methylene compounds *etc*., for a cyanide group, using cyano halides, cyanogen, or aryl cyanates, is described mainly in the patent literature. Operating on contact times of a few seconds, reaction temperatures as high as 1000 °C are proposed.[2–4] The treatment of benzyl cyanide, deprotonated by LDA, with *o*-chlorobenzyl thiocyanate is, owing to mild reaction conditions and high yields, considered to be of some preparative value (Scheme 21).[3] Cyclic 2-cyano ketones may be obtained from the corresponding enolates on treatment with *p*-toluenesulfonyl cyanide.[3]



**Scheme 21**

A closer look has to be taken at the transformation of arenes into cyano derivatives. Aromatic starting materials may for instance be converted into nitriles under Friedel–Crafts conditions. Although a number of variations have been described,[2–4] the preparative value of this process seems to be quite low. The method of Houben and Fischer[2–4] gives rise to quite acceptable yields, but the work-up is very tedious (equation 23).[2]

Aroyl cyanides may be obtained from substrates which are not too electron poor on treatment with cyanogen and HF, when the reaction temperature is slowly raised from –30 to 50 °C.[3] Instead of cyanogen, carbonyl cyanide may also be used,[3] but preparation and handling of this reagent is problematic (equation 24).[3]

High yields of α-cyanoazines are obtained from pyridine, quinoline or isoquinoline *N*-oxides and TMS-CN in acetonitrile/triethylamine or in DMF, and also in THF in the presence of tetrabutylammonium fluoride.[3] In another variation TMS-CN together with dimethylcarbamoyl chloride is used. Mechanistically these transformations should be similar to the Reissert reaction and may run through intermediates of type (**18**) and (**19**; Scheme 22).[3]

### 1.8.1.6 Nitriles From Organometallic Compounds

As many organometallic compounds are prepared from the corresponding halides, their transformation into nitriles may in a way be considered as a substitution reaction.[2–4] Of special use is the treatment of aliphatic or aromatic Grignard compounds with cyanogen or halocyanogen. Aryl cyanates also react with Grignard reagents and usually give excellent yields of the corresponding nitriles (Scheme 23).[3] The reaction of lithium arenes and lithium heterocyclic compounds with *N*-methyl-*N*-phenylcyanamide is probably of only limited value (Scheme 23).[3] It should be mentioned that aluminum compounds may also serve for the preparation of acrylonitrile derivatives.[3]

$$\underset{X\,=\,\text{halogen}}{\text{R-MgX}} \xrightarrow[\text{ii, }H_3O^+]{\text{i, X'CN}} \text{R-CN} \xleftarrow[\text{ii, }H_3O^+]{\text{i, ArOCN}} \text{R-MgX}$$

$$\text{ArLi} \xrightarrow[\text{ii, }H_3O^+]{\text{i, PhNMeCN}} \text{ArCN}$$

**Scheme 23**

## 1.8.2 ISONITRILES

A series of papers from Gauthier and Hofmann, which are cited in nearly every review article on isocyanides,[84–92] is considered the real beginning of scientific work on this class of compounds. Lieke,[88,93] however, seems to have encountered isonitriles earlier. This author reports on 'cyanallyl', which was obtained from mercury cyanide with 1 equiv. of allyl iodide in a sealed tube at 100 °C. This 'cyanallyl' has a highly penetrating and most unpleasant smell'. Opening a vessel of the compound will pollute the air inside a room for several days, which is the reason why all work with this material was done in the open air. Hydrolysis of the compound with alcoholic KOH yielded (after acidification) formic acid and not, as the author had expected, crotonic acid. Lieke finishes: 'There was no more material for further investigations and no possibility of preparing more, as there were complaints about the infernal stink from all over the neighborhood'.[93]

Treatment of alkylating agents with metal cyanides should in principle be the method of choice for preparing isocyanides (equation 25). But as the cyanide ion again represents an ambident nucleophile, the well-known problems already discussed will arise (Section 1.8.2.1.i). It remains to be stated that simple alkylation of alkali metal cyanides with halogen compounds or dialkyl sulfates is not useful for the preparation of isonitriles. The formation of nitriles always prevails and isocyanides are at best obtained in yields of up to 25%.[85–88] The prospects are much better in the alkylation of heavy metal cyanides, if the reaction is done under conditions which initially give rise to isocyanide–transition metal complexes (equation 26). These will then be transformed into isonitriles by treatment with KCN. Under optimized conditions this technique yielded 55% of ethyl isocyanide.[15]

$$\text{R}{-}\text{X} + \underset{\bullet\bullet}{\text{N}}{\equiv}\underset{\bullet\bullet}{\text{C}}^{-}\,\text{M}^{+} \longrightarrow \text{R}{-}\overset{+}{\text{N}}{\equiv}\underset{\bullet\bullet}{\overset{-}{\text{C}}} + \text{MX} \tag{25}$$

$$\text{EtI} \xrightarrow[\text{ii, KCN/}H_2O]{\text{i, AgCN, 100 °C}} \text{Et}{-}\overset{+}{\text{N}}{\equiv}\underset{\bullet\bullet}{\overset{-}{\text{C}}} \tag{26}$$

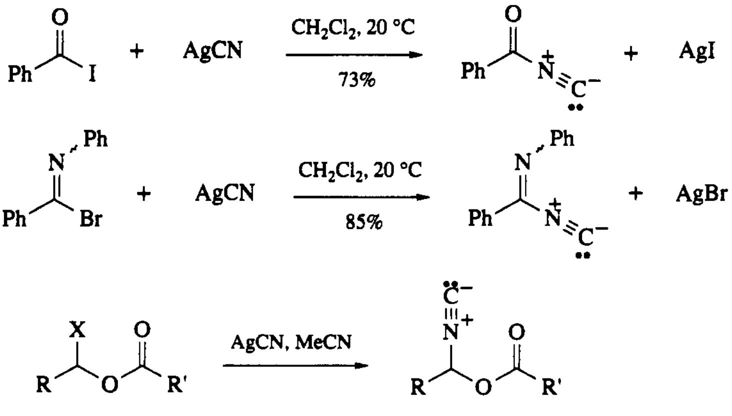
In general, these transformations are run at about 80–100 °C. For preparative use, alkyl iodides proved to be the most useful alkylating agents. CuCN may be used instead of AgCN, in experiments with zinc, cadmium and nickel cyanides; however, a serious decrease in yields was observed.[85–88] Although hexacyano-ferrates and -cobaltates have been recommended in a few cases,[85,88,92] their general use may be rather limited. Remarkable results have, however, been obtained with tetraalkyl- or tetraaryl-ammonium, -phosphonium or -arsonium dicyanoargentates in acetonitrile (Scheme 24).[94] In the diaryl- and triarylmethyl series the bromides or chlorides can be used instead of iodides. The reaction fails, however, with *p*-nitrophenyl derivatives, and aryl iodides and acyl chlorides are not attacked by oniumargentates.

$$2\,\text{MeI} + Ph_4As^+[Ag(CN)_2]^- \longrightarrow 2\,\text{Me}\overset{+}{\text{N}}\overset{-}{\text{C}} + Ph_4As^+[AgI_2]^-$$

$$2\,PhCH_2Br + Me_4N^+[Ag(CN)_2]^- \longrightarrow 2\,PhCH_2\overset{+}{\text{N}}\overset{-}{\text{C}} + Me_4N^+[AgBr_2]^-$$

**Scheme 24**

The quite labile acyl isocyanides on the other hand may be obtained from acyl iodides with AgCN in $CH_2Cl_2$; similarly imidoyl bromides give rise to imidoyl isocyanides (Scheme 25).[95,96] Both types of compounds decompose quite easily under comparatively mild conditions. Acyloxy isocyanides are well known too.[97]

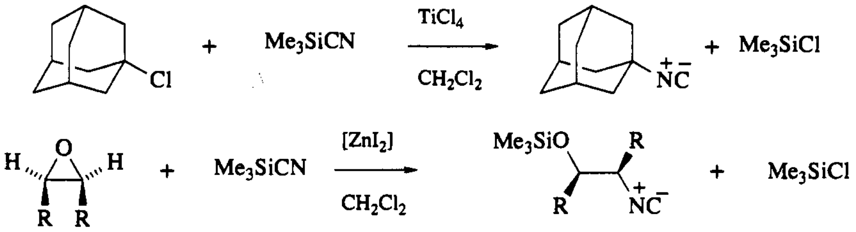


R = Me, X = I, R' = Ph; 79%
R = Ph, X = Br, R' = Bu$^t$; 72%

**Scheme 25**

Silver cyanide is also very useful for the preparation of glycosylisonitriles.[91] Although respectable yields are reported, the reaction is accompanied by anomerization.

In addition to its use in the preparation of nitriles, trimethylsilyl cyanide (TMS-CN) is also becoming a very useful reagent for the preparation of isocyanides. 1-Chloroadamantane, for instance, gives rise to 78% of the corresponding isonitrile in the presence of catalytic amounts of $TiCl_4$ (Scheme 26). Of special interest is the remarkably regioselective and stereoselective synthesis of trimethylsilyloxyalkyl isocyanides (Scheme 26) from oxiranes and TMS-CN in the presence of, for example, zinc halides (see also Section 1.8.1.3).[60,64,65]



**Scheme 26**

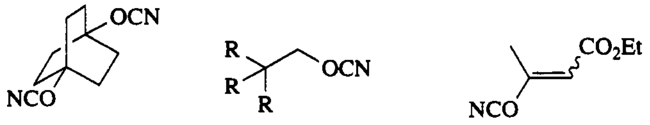
Finally, it should be remembered that isonitriles are not only obtained by substitution processes, but also by alternate routes, which may be of high value. In particular the various techniques for the dehydration of formamides, or the phase transfer version of the classical 'carbylamine' reaction should be noted.[84–92]

## 1.8.3 CYANATES

Attempts to prepare cyanates date back to 1857,[98] but remained unsuccessful for more than 100 years, so that eventually the existence of cyanic esters was questioned. The decisive breakthrough was achieved only about 30 years ago by Stroh and Gerber,[99] when they succeeded in preparing the sterically strongly shielded 2,6-bis(*t*-butylphenyl) cyanate. Today numerous alkyl and aryl cyanates are available and a series of review articles[100–105] provide an excellent overview of the chemistry of this class of compounds. Several tables listing numerous cyanates and the yields from different preparative procedures can be found.[100,103] Discussion of individual examples therefore seems to be unnecessary here. Suffice is to say that, while at the beginning steric protection was believed to be of utmost importance for the stability of the cyanates, it was later realized that sticking to exactly defined reaction conditions is a key measure in preventing secondary reactions.

While aromatic cyanates in their pure state tend to be quite stable compounds, their aliphatic counterparts very often prove to be extremely unstable molecules with an accordingly low preparative value.

Alkyl cyanates are obtained from sterically crowded alcohols or bridgehead derivatives *via* the corresponding alcoholates by treatment with cyanohalides in quite modest yields (Scheme 27). Higher yields and more stable products may be obtained from polyhalogenated alcohols or certain enols. These cyanates show properties comparable to the aromatic series discussed earlier.[106–108]



41% R = Me, 4.4%; R = Cl, 93% 73%
R = F, 80%; R = Br, 85%

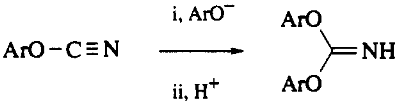
**Scheme 27**

Further reaction procedures leading to alkyl cyanates[102,103] cannot be discussed here. Mention has to be made, however, of the sometimes particularly useful thermal degradation of 5-alkoxy-1,2,3,4-thiatriazoles, which are often only prepared in solution.[102,103]

The aromatic cyanates are of much more importance. If phenols are treated with cyano halides in such a way as to definitely prevent an excess of the corresponding phenolate, aryl cyanates can be isolated in up to quantitative yields. To achieve this, triethylamine is slowly added to an equimolar mixture of the phenol and the cyano halide in a nonprotic solvent, preferably acetone or *n*-pentane/diethyl ether (equation 27).[109] Heteroaromatic hydroxy compounds can be treated in the same way. The method fails, however, if various electron-attracting substituents are present, as for instance with 2,4-dinitrophenol or polyhalophenols.[108]

$$\mathrm{ArOH} \xrightarrow[\mathrm{NEt_3}]{\mathrm{ClCN}} \mathrm{ArO{-}CN} + \mathrm{Et_3\overset{+}{N}H\ Cl^-} \qquad (27)$$

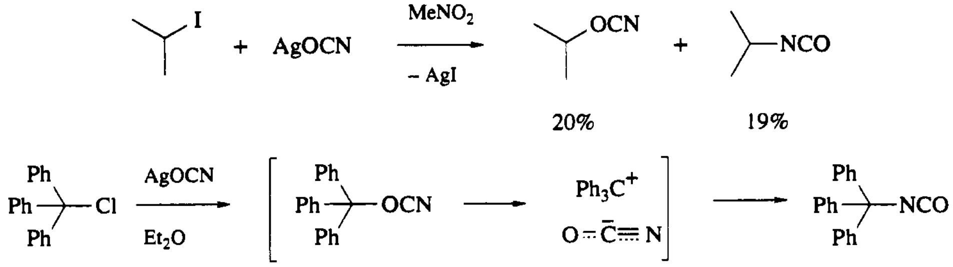
Martin *et al.*[110] report investigations on the kinetics and the mechanism of aryl cyanate formation from cyanogen bromide and phenols in the presence of different tertiary aliphatic amines. According to Vowinkel,[111] the use of diethyl ether as the solvent at –10 °C raises the yields and various patents describe how the amines can be replaced by sodium hydroxide. There are even reports on work in aqueous solution under phase transfer conditions.[103] With all synthetic variants it is crucial to avoid a surplus of the phenolate as only under these conditions can the often quite fast formation of imino carbonates be prevented (equation 28).



$$\mathrm{ArO{-}C{\equiv}N} \xrightarrow[\text{ii, H}^+]{\text{i, ArO}^-} (\mathrm{ArO})_2\mathrm{C{=}NH}$$

(28)

Treatment of alkyl halides with alkali metal or silver cyanate is of no preparative value for the synthesis of cyanates.[103,112,113] As cyanate ions do represent ambident nucleophiles, Holm and Wentrup[114] tried to reach cyanates under well-defined $S_N1$ conditions (Scheme 28). But even treatment of isopropyl iodide with silver cyanate in nitromethane provided only a very low yield of a 1:1 mixture of isopropyl cyanate and the corresponding isocyanate, and from a reaction of silver cyanate with triphenylchloromethane they isolated only triphenylmethyl isocyanate, although the cyanate may have been an intermediate in this transformation.[114]



**Scheme 28**

## 1.8.4 AZIDES

### 1.8.4.1 General Remarks

The history of the azides starts in 1864 with the first report on phenyl azide by Griess.[115] In 1990, the first preparation of hydrazoic acid by Curtius had its 100th anniversary.[116] There are many reports on aliphatic and aromatic azides in the literature. In a very recent and thorough review[117] Scriven and Turnbull present a highly impressive list of review articles which have appeared in the 20 years since 1970. Out of the many possibilities for preparing all types of azides, substitution reactions are of special importance. Here again a series of recent review articles[117–123] will guarantee a quick orientation in the field.

### 1.8.4.2 Azides from Halogen, Sulfonate and Sulfate Derivatives

#### *1.8.4.2.1 Alkyl azides*

The reaction of halides or sulfonates with alkali metal azides, mostly $NaN_3$, offers a simple and high yield access to alkyl azides.[118,119] For the preparation of the most simple ones, *e.g.* methyl and ethyl azide, the corresponding sulfates were for a long time considered the only useful starting materials.[118,119] The preparation of azidoethane in ether solution from ethyl iodide and $NaN_3$ was reported recently (Scheme 29).[124] Alkane- and *p*-toluene-sulfonates are well-established starting materials for the preparation of azido carbohydrates.[117,119] Their particular importance rests mainly on the possibility for reductive generation of amino sugars. The crucial role of alkanesulfonates for the generation of alkyl azides is demonstrated by Scriven and Turnbull[117] with numerous examples.

$$R{-}X \quad + \quad N_3^- \longrightarrow R{-}N_3 \quad + \quad X^-$$

$$X = \text{halogen, } OSO_2R', OSO_2OR'$$

$$EtI \quad + \quad NaN_3 \xrightarrow[Et_2O/H_2O]{Bu_4N^+\,BF_4^-} EtN_3 \quad + \quad NaI$$

**Scheme 29**

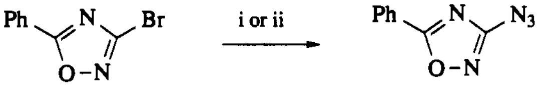
If alkyl halides are used as starting materials, one is not restricted to iodides, as bromides and chlorides may also be used. So-called activated $NaN_3$[118,119,125] or $AgN_3$ is only necessary in special cases, and may then, however, prove to be of particular advantage.[118] Besides primary alkyl halides, secondary ones may also be considered as starting materials and even some tertiary azides were prepared this way.[117] Some experimental details can be found in Grundmann's review;[118] tables with numerous examples[118,119] provide a very good impression of the scope of this transformation. The high tendency for explosions of many azides, particularly the lower ones, is a good reason to generate and transform these compounds, whenever possible, in solution only.

For a long time protic solvents like methanol or water at temperatures between 60 and 100 °C were considered best. 2-Alkoxyethanols ('carbitols') with their higher boiling points have in the meantime become quite popular.[118,119] Of course dipolar aprotic solvents like DMSO, DMF and also nitrobenzene may be used for the preparation of azides too, although the isolation of reaction products may sometimes be difficult here.[117] Given slowly reacting substrates, the higher solubility of $LiN_3$ may in certain cases provide advantages compared to other alkali metal azides.[117] A combination of $NaN_3$ and $ZnCl_2$ is often recommended, particularly for the generation of tertiary azides.[117,126]

The various phase transfer techniques also led to very good results in azide synthesis. Excellent yields of alkyl azides were secured, for instance, when alkyl bromides were treated with alkali metal azides in the presence of catalytic amounts of tetrabutylammonium bromide or 'aliquat 336' (equation 29).[117,127] The use of crown ethers has been described as well.[117]

A very impressive example consists of the preparation of 3-azido-1,2,4-oxadiazole, which after a series of failures was eventually obtained from the corresponding bromo compound with $LiN_3$ in dry DMF or with $KN_3$ in the presence of 18-crown-6 (Scheme 30).[128]

$$\underset{\mathrm{R = alkyl}}{\mathrm{R{-}Br}} + \mathrm{NaN_3} \xrightarrow[\sim 90\%]{\mathrm{H_2O/aliquat\ 336}} \mathrm{R{-}N_3} + \mathrm{NaBr} \qquad (29)$$



no reaction with:
$NaN_3$, DMF/$H_2O$, 100°C;
$NaN_3$/NaI, 50 °C;
$LiN_3$, MeOH, 65 °C;
$Bu_4N^+N_3^-$, MeCN, 83 °C

Scheme 30

The acceleration of substitution reactions with azides using ultrasound techniques (Scheme 31) has not yet been investigated in detail.[129] Activated primary halides react with trimethylsilyl azide (TMS-A) under particularly mild and absolutely neutral conditions (Scheme 31).[117] Secondary and tertiary cyclic halides were treated with TMS-A/$SnCl_4$ in $CH_2Cl_2$ or $CHCl_3$ to yield the corresponding azido compounds.[117] Very impressive results with yields of about 90% were in this case reported in the adamantane and diamantane series.[117] High solubility in organic solvents is also noticed with acetyl azide, which, prepared *in situ*, has also been used for azide syntheses. The scope of this reaction has still to be determined, however.[117] Hassner[130] noticed nearly quantitative yields of azides when alkyl halides (or tosylates) were treated with polymeric quaternary ammonium azides.

$$\mathrm{R{-}X} + \mathrm{NaN_3} \xrightarrow{\mathrm{H_2O,\ ultrasound}} \mathrm{R{-}N_3} + \mathrm{NaX}$$

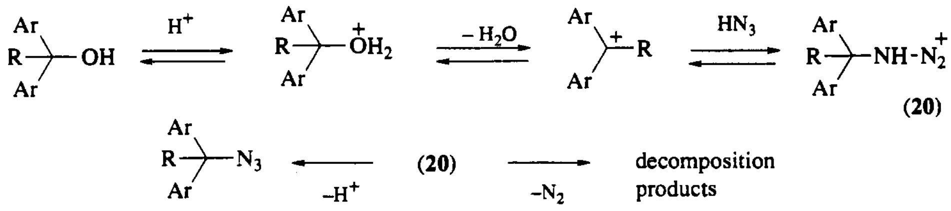
R = $ArCH_2$, $R'_2C{=}CHCH_2$, $NCCH_2$, $EtO_2CCH_2$; 60–87%

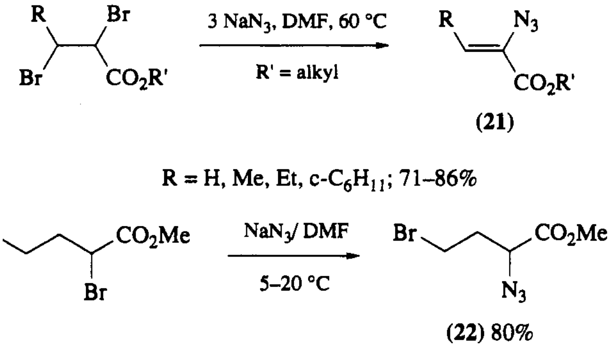
Scheme 31

Mechanistically most of these transformations correspond to $S_N2$-type substitutions; chiral substrates react with inversion. In certain cases, however, azides may also be obtained under $S_N1$ conditions.[118,119,126b] Some di- and tri-arylmethanols for instance (Scheme 32) react with $HN_3$ in the presence of trichloroacetic acid *via* the corresponding carbenium ions. Sulfuric acid seems to be inferior for these transformations.[118,119] Under highly acidic conditions the intermediate (**20**) obviously tends to decompose with the elimination of nitrogen (*cf.* Schmidt reaction[117]). $S_N1$ substitution is also highly probable in the reaction of α-halo ethers and sulfides with azide ions.[118,119] In some cases even $S_{RN}1$-type substitution was observed for the halogen/azide exchange.[117]



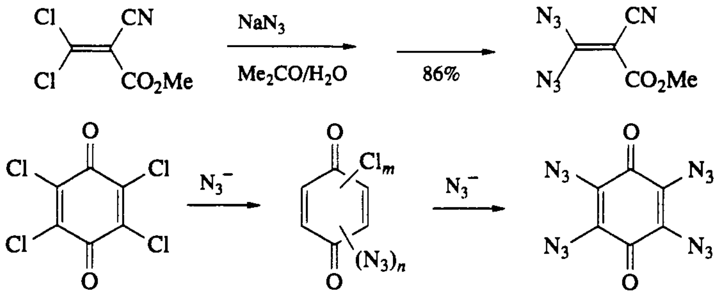
Scheme 32

By starting from the corresponding dihalides, diazides may also be obtained with ease. A list of numerous examples is given by Grundmann.[118] The high tendency of some diazides to explode, has to be mentioned here. For a demonstration of the strong influence of structural parameters on the reactivity of dihalides with azide ions[117] two examples will suffice (Scheme 33): in a sequence of elimination, addition (Michael acceptor) and substitution steps, followed by another β-elimination, 2,3-dibromocarboxylic esters give rise to high yields of the vinyl azides (**21**) with 3 equiv. of $NaN_3$; on the other hand, methyl 2,4-dibromobutanoate yields 80% of the monoazido ester (**22**) with only a very small amount of the corresponding bisazido compound.[131]



Scheme 33

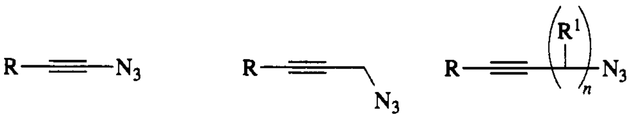
Vinyl azides are generally prepared from 2-azido halides by elimination,[118,119,132,133] while vinylogous acid chlorides and similar systems may be treated with azide ions directly in an addition–elimination sequence (Scheme 34). With haloquinones smooth transformations into azidoquinones are also observed.[118,119,134,135] Thus all four chloro substituents of chloranil can be successively exchanged with azide ions (Scheme 34).



$m = 3, 2, 1$
$n = 1, 2, 3$

Scheme 34

There is still no successful approach to 1-azidoalkynes, although the corresponding phenyl derivative (**23**; Scheme 35) is thought to be a short-lived intermediate in the reaction of chlorophenylacetylene with azide ions.[117,118] In contrast to this, propargylic azide (**24**) and its higher homologs (**25**) can be obtained in the usual way.[117] The formation of these compounds is sometimes accompanied by rearrangements, which also very often take place with azidoallene derivatives; their chemistry was intensively studied recently by Priebe[117] and Banert.[136]



(**23**) R = Ph (**24**) (**25**)

Scheme 35

Mechanistically, there is a range of possibilities for the reaction of allylic halides with azide ions, with many details still open for discussion.[117,119] Besides simple substitution reactions, depending on the structure of the starting materials and the experimental conditions, allylic rearrangements as well as equilibration reactions may be observed.[117,119]

Nucleophilic substitution of functionalized halides may also lead to azides, carrying further functional groups, not only in the 'periphery' of the molecule, but also in the very close neighborhood (α-position). A few examples have been mentioned already. Quite well known are, for instance, α-azido-alkylamines, -carboxylic acid derivatives, ethers, sulfides and ketones, which can be quite simply obtained from the corresponding halo compounds.[117,118] The observation that the chiral substrate (**26**) undergoes the substitution reaction, if tetramethylguanidinium azide is used, with less than 1% epimerization (Scheme 36)[137] merits special interest. In the interaction of azide ions with 3-hydroxy-2-halocarboxylic esters, a rearrangement *via* oxiranes may take place (Scheme 36).[118] Aiming at a stereoselective synthesis of the corresponding amines, a series of azide steroids was prepared,[117,119] starting from the halo derivatives or the corresponding sulfonates. In most cases an $S_N2$-type process, leading to stereochemically well-defined products, was observed.

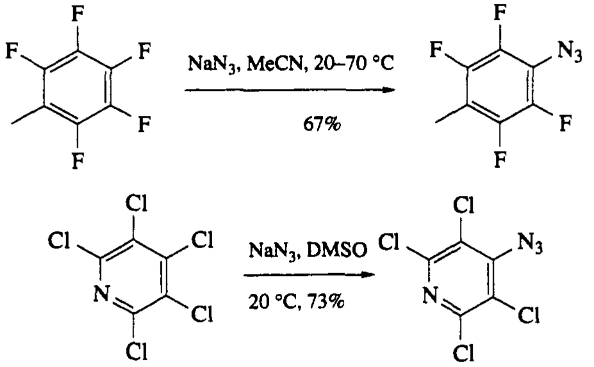
**Scheme 36**

### *1.8.4.2.2 Aryl azides*

The synthesis of aromatic azides (Scheme 37) from aryl halides with azide ions ($S_NAr$) is particularly successful with systems that carry an activating substituent, an electron-withdrawing group, either in the *ortho* or the *para* position relative to the potential leaving group.[118,119] A table with numerous examples can be found in the literature.[119] Fluoride ion as a leaving group is superior to the other halides. Dipolar aprotic solvents, such as DMF for instance, have their special merits in these transformations, too. The reaction of 2,4- or 2,6-dinitroaryl halides with azide ions was shown to be accelerated in micelles or in the presence of quaternary ammonium salts.[117]

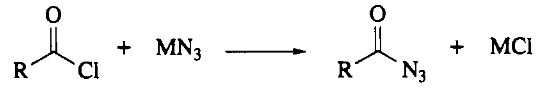


**Scheme 37**

Various perhalo aromatic compounds as well as a series of heterocyclic precursors, such as, for instance, chloro-pyridazine or -triazine derivatives, gave rise to the corresponding azides, too.[117,119,121]

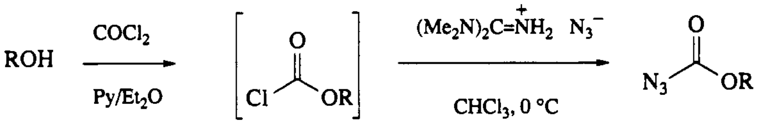
### 1.8.4.2.3 Acyl azides

The preparation of acyl azides by substitution is presented in connection with the Curtius rearrangement in a series of review articles.[117-121,125,138] The most important synthetic methods are discussed in the sequel. The routine technique for the generation of various acyl azides by substitution starts from acyl chlorides and azide ions (equation 30).[119-121,125] The reactions are generally run by mixing an aqueous solution of the azide, mostly $NaN_3$, with a solution of the acid chloride in a water-miscible solvent such as acetone, alcohols, dioxane, HOAc or DMF. The competing solvolysis of the acyl chloride with alcohols must be considered. In certain cases the use of tertiary amines or amine oxides as catalysts is recommended.[120] If suspensions of $NaN_3$ in organic solvents such as pyridine, toluene, xylene or nitrobenzene are used, reaction temperatures often have to be used that lead to the Curtius rearrangement of the required acyl azide.[119,120] In this case the use of 'activated' $NaN_3$ is recommended.[118] Advantages are seen by using $LiN_3$ in DMF,[139] mainly due to its better solubility, and the same holds for a series of tetraalkylammonium azides, which in many cases are thermally quite stable, too.[120] DMSO cannot be used as the solvent here, as it reacts with acyl chlorides quite vigorously at room temperature.[119]



(30)

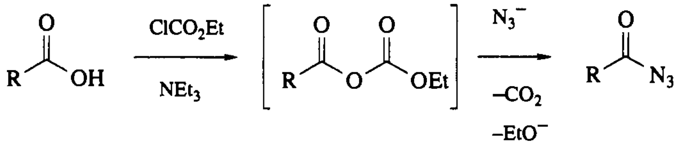
The reaction of acid chlorides with tetramethylguanidinium azide also proceeds under very mild conditions.[140] Using this technique even *t*-alkyl azidoformates may be prepared (Scheme 38). Quantitative yields of acyl azides (in solution) are reported for the interaction of acid chlorides in toluene with $HN_3$/pyridine at 0 °C. Even sterically hindered educts are smoothly converted into acyl azides.[121] If tetraalkylammonium azides are used, the use of hazardous hydrazoic acid is avoided.[120,121]



R = Bu$^t$, ~100%; R = *t*-amyl, 84%; R = Ph, 97%

**Scheme 38**

It should be mentioned at this stage that instead of acyl chlorides, mixed anhydrides may also be used for the synthesis of acyl azides. From carboxylic acids and chloroformates/triethylamine, mixed anhydrides are formed, which can directly react with azide ions. Sterically hindered acids fail in this procedure (equation 31).[119-121] The similar synthesis of *t*-butyl azidoformate by reaction of *t*-butylcarbonic diethylphosphoric anhydride with $KN_3$ is described in *Organic Syntheses.*[141]



(31)

In synthesizing α,β-epoxyacyl azides Zwanenburg *et al.*[142] noted that treatment of the acid chloride (**28**) with $HN_3$/pyridine is superior to the reaction of mixed anhydrides (**27**), prepared *in situ*, with $NaN_3$ (Scheme 39). Another version of this process uses the transformation of acyloxyiminium salts of type (**29**) (again prepared *in situ*) with $NaN_3$ (Scheme 39).[143] The authors did not isolate the azido derivatives, but used them in a subsequent Curtius rearrangement in boiling toluene. After a final treatment with aniline, yields of the corresponding ureas were between 60 and 80% with alkyl compounds and 86–100% for aryl systems. Palomo *et al.*[144] used a very similar procedure and were able to isolate the azides.

Trimethylsilyl azide (TMS-A) in the presence of catalytic amounts of pyridine turned out to be very useful in the preparation of acyl azides, as this reagent will not only transform acyl chlorides and mixed anhydrides into azides, but also works with reactive esters and lactones (Scheme 40).[121,145] Many of these reactions have, however, been run under conditions which will lead to the Curtius rearrangement of the azide intermediates. Pyridine as a catalyst can be replaced by the combination $KN_3$/18-crown-6.[121] Diazidodiphenylsilane, which was investigated as well, will probably not become a standard reagent.[145]

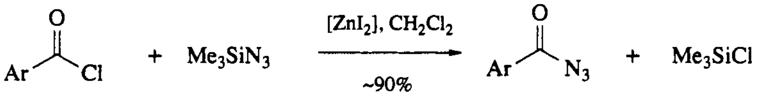
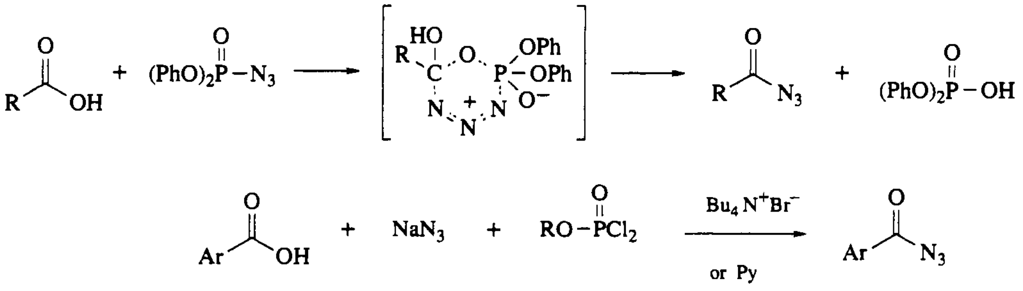
**Scheme 40**

The transformation of aroyl chlorides with TMS-A can be run at 0 °C if a catalytic amount of $ZnI_2$ is used in $CH_2Cl_2$ (equation 32). This provides a simple and high-yielding route to aroyl azides, which may be isolated in a pure state.[146] Electron-donating groups in the aryl group retard the reaction, without, however, influencing yields.



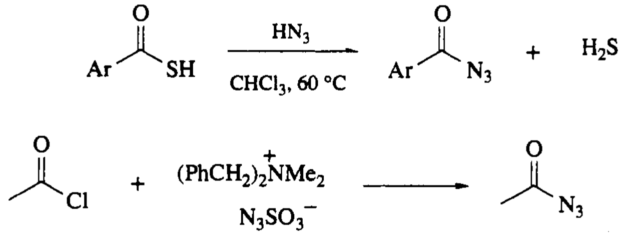
(32)

In a direct route from carboxylic acids to acyl azides diphenyl phosphorazidate is used;[121] probably the reaction passes through a cyclic transition state (Scheme 41). With aromatic and heteroaromatic educts, yields as high as 75% may be obtained.[147] If aliphatic acids are treated under the same conditions, the corresponding azides are, however, immediately transformed into urethanes *via* isocyanates.[148] Aroyl azides can also be obtained in excellent yields by reaction of carboxylic acids with $NaN_3$ and phenyl dichlorophosphate in the presence of tetrabutylammonium bromide or pyridine (Scheme 41).[149]



**Scheme 41**

The preparation of acid azides from thiocarboxylic acids/$HN_3$ or from acyl chlorides with dibenzyldimethylammonium azidosulfonate[119] has not yet found broad application (Scheme 42).

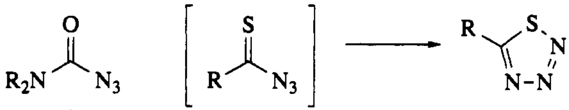


**Scheme 42**

There are great differences in the thermal stabilities of acyl azides. While the aromatic derivatives are considered to be comparatively stable, their aliphatic counterparts very often decompose close to room temperature. As in the course of this destruction the preparatively most useful Curtius rearrangement will take place, this instability is not necessarily a disadvantage.

Owing to the unpredictable tendency of most azides to explode suddenly, it is essential in the preparation of acyl azides to pay strict attention to the necessary precautions.

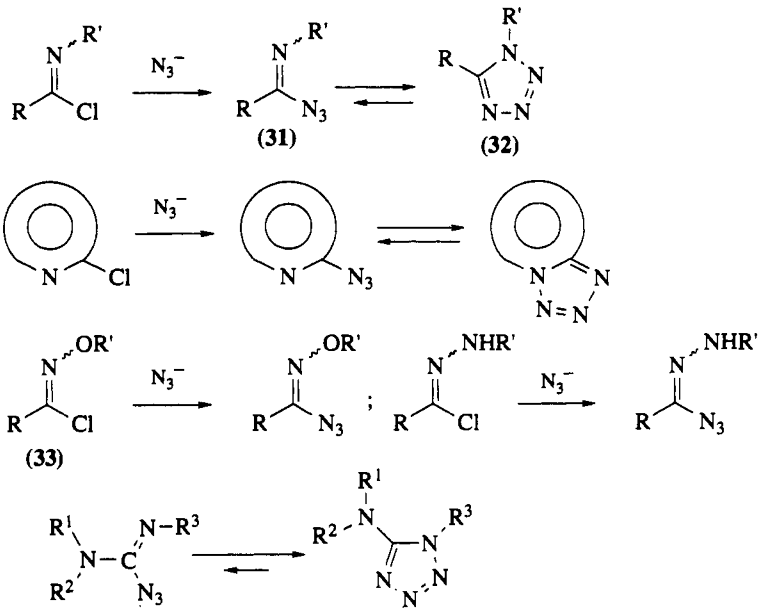
As demonstrated above, azidoformates, which, like the very similar carbamoyl azides (**30**; equation 33),[119,120,150] play an important role in peptide chemistry and as nitrene precursors,[119,120] can be generated in the usual way. Their thermal stability is generally higher than that of alkanoyl and aroyl azides. The tendency of acyl azides to form 1,2,3,4-oxatriazoles in a cyclization process is extremely low. In contrast to this thioacyl azides, which are only generated on treatment of thioxohydrazides with nitrous acid, seem to be only very short-lived intermediates, which immediately form 1,2,3,4-thiatriazoles as stable end products.[120]



**(30)** (33)

### 1.8.4.2.4 *Further azides of the type RC(=X)N₃*

In the reaction of imidoyl halides with azide ions, imidoyl azides (**31**) are obtained, which caused some interest on account of their ring–chain tautomerism (**31**)/(**32**) (Scheme 43).[119,120] It is not possible, however, to discuss this point in detail here.[117,120,151] The final elucidation of a series of dubious structural assignments had to wait until the advent of modern spectroscopic methods. As expected, the position of this equilibrium is influenced by the nature of substituents R/R′ as well as by temperature and solvents. Electron-withdrawing ligands seem to favor the formation of the tetrazole isomer (**32**). The equilibrium (**31**)/(**32**) does not always operate — there are a number of cases known which show a comparatively high activation barrier.[120] The same problems are encountered with the reaction products from 2-halo-azoles and -azines with azide ions.[118–120]



**(31)** **(32)** **(33)** **(34)**

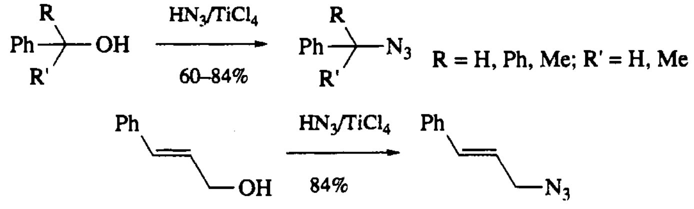
**Scheme 43**

In a similar way to azidoazomethines, the corresponding azido oximes and hydrazides may be obtained (Scheme 43). The formation of cyclic tautomers seems to play only a minor role here.[117,119,120,152] The stereochemical aspects of the transformation of *O*-acylhydroxamoyl chlorides (**33**; R = $^-$Ac) with $N_3$ ions have been studied by Hegarty.[153] Further systems such as the interesting pairs guanyl azides (**34**)/5-aminotetrazoles, are comprehensively discussed by Lwowski.[120]

## 1.8.4.3 Azides by Exchange of Oxygen or Sulfur Functionality

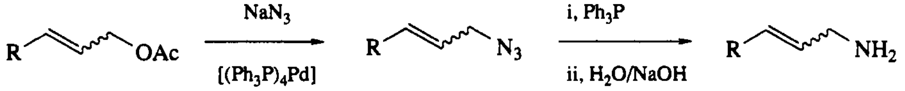
Alcohols may be used in various ways as starting materials for azides. The well-known transformations *via* alkyl halides and sulfonates need not be discussed at this stage again (see Section 1.8.4.2.1). The activation of alcohols *via* phosphonium salts has found application in the carbohydrate series.[117]

The $S_N1$-type transformation of secondary and tertiary alkanols with the help of trichloroacetic acid and hydrazoic acid has also been mentioned in Section 1.8.4.2.1. Several azides, *e.g.* of the adamantane and diamantane series, have been obtained on treatment of the corresponding alcohols with $NaN_3$ and sulfuric acid.[154] As expected, this procedure lends itself particularly well to the formation of tertiary azides.[117] Treatment of tertiary carbinols with $HN_3$ and $BF_3$ or other Lewis acids represents another route to tertiary azido compounds.[117] On the other hand, with primary alcohols this procedure only succeeded when benzylic or allylic alcohols were used (Scheme 44), an observation which, together with the partial racemization noticed in the case of chiral educts, hints at carbenium ion intermediates.[117]



Scheme 44

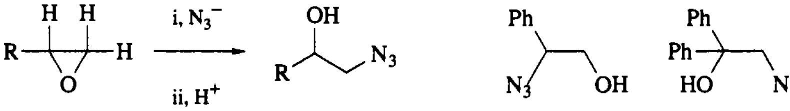
Walden inversion, on the other hand, is observed in the reaction of alkanols with diethyl azodicarboxylate, triphenylphosphine and $HN_3$ (*cf.* the Mitsunobu reaction).[117,155] There is also some interest in the Pd-catalyzed transformation of allyl acetates into the corresponding azido derivatives.[156] Primary amines can be generated in a one-pot procedure without isolation of these azides, by further treatment with $Ph_3P$ and subsequent hydrolysis (Scheme 45).



Scheme 45

The direct transformation of carboxylic acids into azides and the ring fission of β-lactones have been discussed in Section 1.8.4.2.3.

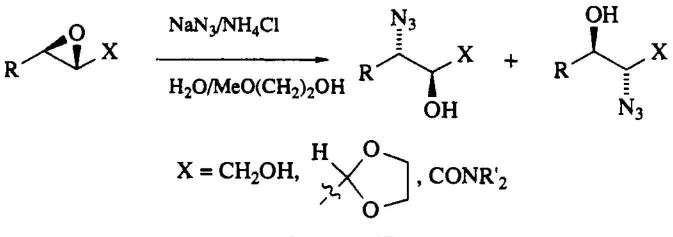
Opening of epoxides with azide ions represents a very interesting route to azidocarbinols. The large number of examples quoted in the literature proves the broad scope of this technique.[117-119,157] On treatment of nonsymmetrically substituted oxiranes, the products expected from an $S_N2$ process are usually obtained. In boiling aqueous dioxane, cyclohexene oxide gives rise to 61% of *trans*-2-azidocyclohexanol. The reported formation of (**35**; Scheme 46) with styrene oxide is unexpected,[158b] particularly if the formation of (**36**) from the analogous diphenyl precursor is considered.[158]



(**35**) 63% (**36**) 73%

Scheme 46

In a recent very thorough investigation, Behrens and Sharpless studied the possibilities for the selective transformation of 2,3-epoxy-carbinols, -acetals and -amides into azidoalkanols (Scheme 47).[159] The regioselectivity of this process turned out to be strongly dependent on steric as well as electronic parameters; it is not possible to discuss details here.



Scheme 47

The special merits of solid-supported sodium azide reagents were intensely investigated recently. Under well-defined reaction conditions very high regioselectivity may be achieved with nonsymmetrically substituted oxiranes.[160] A new approach to an especially mild and selective synthesis of 3-azidodiols was recently described, which involves a highly regio- and stereo-selective ring fission of epoxy alcohols, using TMS-A and $Et_2AlF$ (Scheme 48).[161] For comparison, some results with $NaN_3/NH_4Cl$ are also included.

α-Azido ethers or even diazides can be obtained on treatment of acetals with $TMS\text{-}A/SnCl_4$ (Scheme 49).[162,163] TMS-A proved also to be the best reagent for the transformation of orthoesters (cyclic ones included) into the corresponding azido derivatives.[164] Cationic species are considered as intermediates.

Thioketals reacted with $IN_3$ to give α-azido sulfides or 1,1-diazides.[165] Treatment of the azido sulfides (**37**) with $SnCl_4$ led to the corresponding imino sulfides; these were also available directly from the thioketals (probably *via* azido sulfides) by reaction with $NaN_3/SnCl_4$ or with $TMS\text{-}A/SnCl_4$ and a catalytic amount of iodine (Scheme 50).

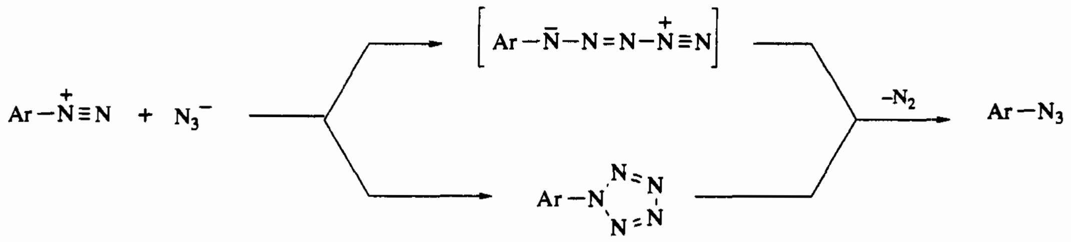
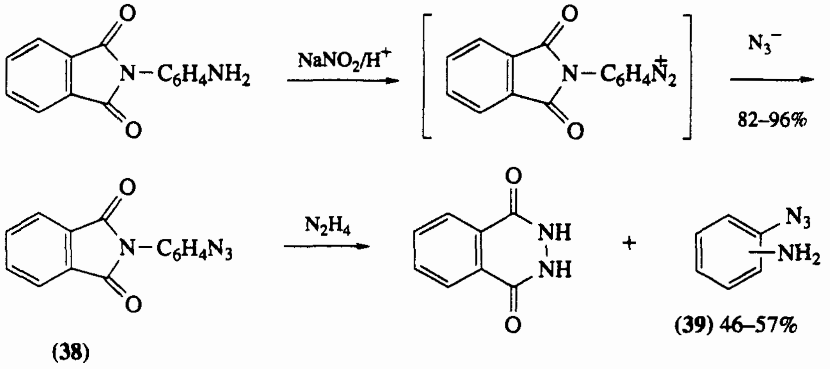
### 1.8.4.4 Azides by Exchange of Nitrogen Functionality

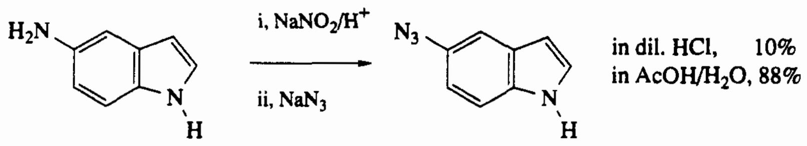
In an interesting technique for the preparation of aromatic azides, aryl diazonium salts are treated with azide ions.[117-119] At least in a very formal sense, one can consider this reaction as a substitution process, although the real mechanism of this transformation is much more complicated.[166] An excellent discussion of the mechanistic aspects of the reaction sequence is presented by Biffin *et al.*[119] Without going into details, Scheme 51 illustrates the chemistry involved. The preparative significance becomes obvious from a published table with about 15 examples; sometimes yields of more than 90% were obtained.[119] The aromatic ligand may carry a number of further functional groups and di- or tri-azides can be formed as well as heterocyclic azides. Starting with *N*-(aminophenyl)phthalimide, the azido derivative (**38**) is obtained *via* diazotization, followed by reaction with $HN_3$. Hydrazinolysis of the protecting phthaloyl group (Scheme 52) yields the otherwise inaccesible azidoanilines (**39**).[119] With the 4-, 5- or 6-aminoindoles a remarkable increase of azide yields was noticed when the formation of the diazonium salts was performed in 80% HOAc instead of diluted mineral acids (Scheme 53).[167]



**Scheme 51**



**Scheme 52**



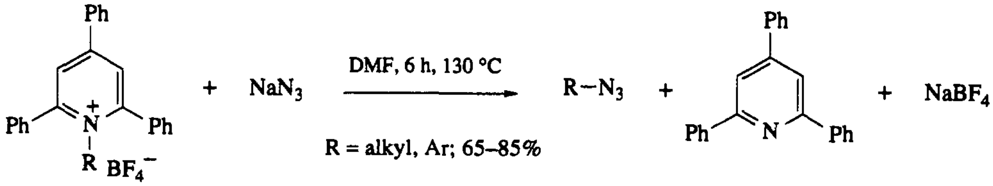
**Scheme 53**

Provided the starting materials are easy to obtain, the interesting reductive substitution of aromatic nitroso compounds (Scheme 54) is also a useful preparative technique.[118,119,168] The mechanistic aspects of the reaction sequence have been discussed.[119]

$$\mathrm{Ar{-}N{=}O} \xrightarrow{\mathrm{HN_3}} \left[\mathrm{Ar{-}N{=}N{-}OH}\right] \xrightarrow[\mathrm{-N_2}]{\mathrm{HN_3}} \mathrm{Ar{-}N_3}$$

**Scheme 54**

*N*-Alkyl and -benzyl substituents can be displaced from 2,4,6-triphenylpyridinium tetrafluoroborates by reaction with azide ions (Scheme 55). This method enables the conversion of primary alkyl- or benzyl-amines to the corresponding azides.[169]



Scheme 55

### 1.8.4.5 Azides by Azide Transfer Reactions

The synthesis of various azido compounds with arene sulfonyl azides has, at least in a formal sense, to be considered as an electrophilic substitution of hydrogen by an azide function.[117,119,122] By this route a number of amines, cyclic derivatives and bridgehead compounds included, after deprotonation with NaH or Grignard reagents, could be transformed into azides in high yield on treatment with arene sulfonyl azides.[117,170] Details cannot be given here. Enolates can also be converted into azido derivatives in a very similar way, *via* triazene intermediates.[117] Evans *et al.*[171] did recently investigate the influence of the countercation, the structure of the transfer azide and work-up conditions on this process.

## ACKNOWLEDGMENTS

The author is especially grateful to Dr. U. Tilstam, University of Hannover, for the translation of the German manuscript and to Mrs. Krystina Becker, University of Munich, for technical assistance.

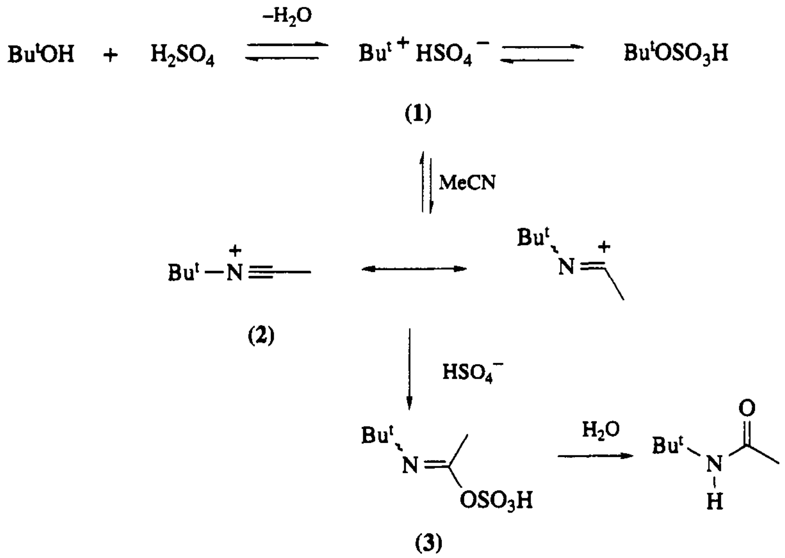
## 1.9.1 THE RITTER REACTION

The process now known as the Ritter reaction was first described in detail in two papers[1,2] published in 1948. Strongly acidic conditions were used to generate a carbenium ion which underwent nucleophilic attack by a nitrile, and further events leading to the isolated product. In its original and most familiar form, hydrolytic work-up produced an amide. However, later investigations showed that in suitable cases intramolecular cyclization could occur, affording a wide range of heterocyclic materials. Although this very general reaction is justly named for Ritter, who recognized and explored its considerable potential, it is not surprising that a few special cases of Ritter-type processes are described in earlier independent reports.[3–7] Early work on the Ritter reaction is well served by a number of review articles,[8–14] that by Krimen and Cota[12] being especially valuable in the present context.

### 1.9.1.1 Reaction Mechanism

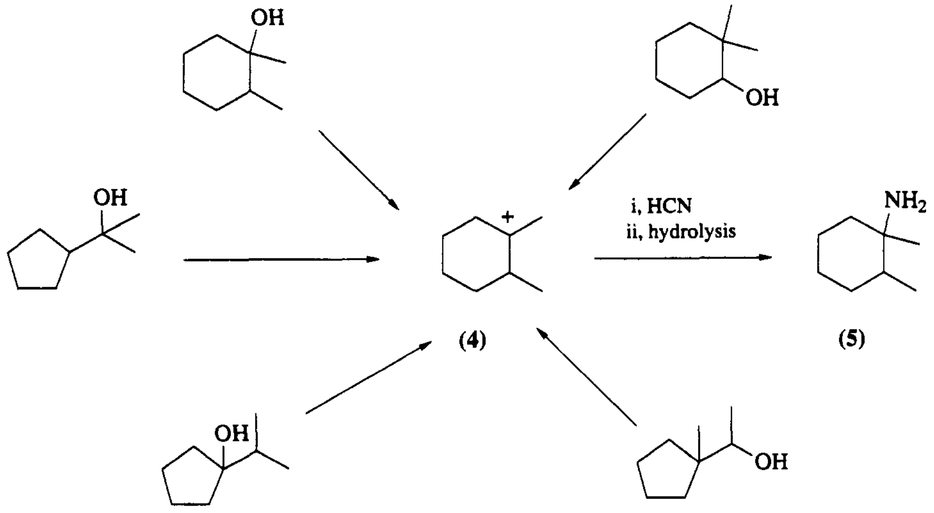
The mechanism of the reaction is illustrated in Scheme 1 for the conversion of *t*-butanol, using sulfuric acid and acetonitrile, into *N*-*t*-butylacetamide. Three intermediates are involved. Firstly, a carbenium ion (**1**) is produced under strongly acidic conditions. This reacts with the nitrile to produce a resonance-stabilized nitrilium ion (**2**), which in turn is converted into the corresponding imidate (**3**). Finally, the latter is hydrolyzed to the amide. Since all three events occur in a one-pot process, frequently in high yield, the Ritter reaction is a simple, efficient and general synthetic procedure.



**Scheme 1**

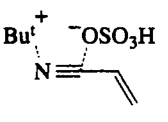
As an alternative to amide formation, intramolecular cyclizations involving the nitrilium ion lead to a variety of heterocyclic systems (Section 1.9.2). Since carbenium ions, or their equivalents, may be produced by means other than strong acid, a number of valuable extensions of the original reaction are possible (Section 1.9.3). In addition, nitrilium and imidate species are also available through other processes, implying that the Ritter reaction has close mechanistic relationships with other well-established reactions and with the chemistry of the isonitriles. These aspects are explored in Section 1.9.4.

The essential details of the reaction mechanism were originally proposed by Ritter and his collaborators,[2,15] and only a brief description of the work supporting this reaction pathway will be presented here. Replacement of the nitrile with the corresponding amide resulted in failure of the reaction, demonstrating that addition of the amide and carbenium ion was not involved.[1] As part of a detailed study using oleic acid, Roe and Swern[16] were not only able to use a variety of acidic media to obtain amide products, but evidence of isomerization due to carbenium ion intermediates was also presented. This expected feature of the above mechanism was thoroughly investigated by Christol, a good illustration[17] of such rearrangement being formation of cation (4), and subsequent isolation of the amine (5), from each of the five alcohol precursors shown in Scheme 2.



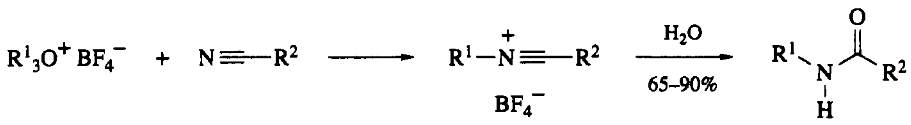
**Scheme 2**

Kinetic measurements on the reaction between *t*-butanol and acrylonitrile in 20–69% sulfuric acid showed it to be first order with respect to both reagents. This led Deno[18] to suggest that the transition state involved nucleophilic attack by the nitrile on the protonated alcohol. However, the latter might better be regarded as a weakly solvated carbenium ion and the process as an '$S_N$ intermediate' reaction.[19] In a later related study (isobutene and acrylonitrile) Glikmans[20] concluded that the reaction involved an ion pair and that the nitrile was associated with both partners in the transition state (**6**). Nitriles are only about half-protonated in 89–100% sulfuric acid and, therefore, nucleophilic behavior presents no difficulty.[21] Retro-Ritter reaction can occur when an *N*-*t*-alkylamide is treated with dehydrating agents such as thionyl chloride or phosphorus(V) oxide.[22] Carbenium ions generated by nonacidic routes also react with nitriles and yield amides on hydrolytic work-up (Section 1.9.3).



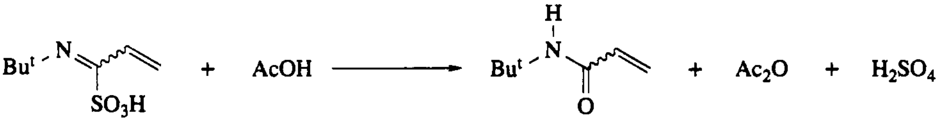
(**6**)

Evidence supporting the involvement of nitrilium ion intermediates is available from the large number of heterocyclic derivatives obtained by intramolecular trapping reactions.[14] Furthermore, independently generated nitrilium salts[23] undergo hydrolysis to Ritter products (Scheme 3).

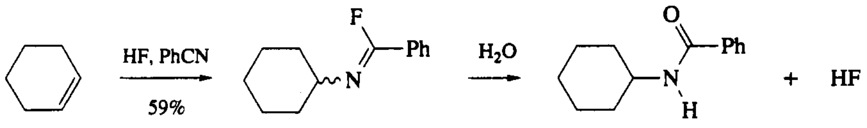


**Scheme 3**

Definitive evidence for the imidate intermediate was provided by Glikmans[24] in 1966. Reaction between isobutene and acrylonitrile in anhydrous acetic acid containing 100% sulfuric acid allowed isolation and characterization of (**7**), which was readily hydrolyzed to the corresponding amide by dehydration of acetic acid (equation 1). Subsequent work by Norell[25] on reactions of alkenes with nitriles in anhydrous liquid hydrogen fluoride allowed isolation of imidoyl fluorides such as (**8**) for the first time. Such materials, obtained pure and fully characterized, react instantly with water to yield the amide (Scheme 4).



(**7**) (1)



(**8**)

**Scheme 4**

### 1.9.1.2 Reaction Conditions

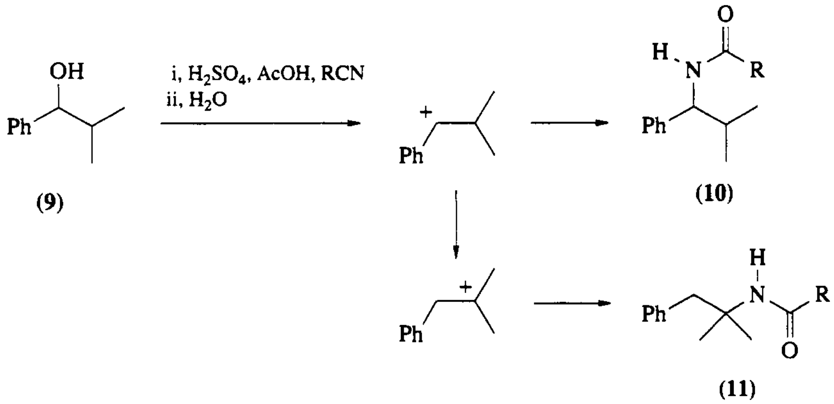
The precise experimental conditions used can greatly influence the efficiency, or even the course, of the Ritter reaction. Representative procedures are available, along with a comprehensive tabular survey to 1966, in the article by Krimen and Cota.[12] Optimum reaction times (typically 1–24 h) and temperatures (typically 20–50 °C) depend very much on the particular cases. Typical temperatures of 0–10 °C are used when hydrogen cyanide or hydrogen fluoride are employed. Benzenesulfonic, fluoroboric, formic, hydrofluoric, methanesulfonic, perchloric, phosphoric, polyphosphoric, sulfuric, toluenesulfonic and trifluoromethanesulfonic acids are amongst those used to generate the carbenium ion. However, the majority of workers favor sulfuric acid and, in cases where comparative studies have been carried out,[16,24,26] this reagent generally gave the best yields. This may reflect participation of the hydrogensulfate ion during attack by the nitrile reagent.

The best acid concentration depends on the type of substrate[26] but usually 85–90% sulfuric acid is employed. Similarly, for hydrofluoric acid the optimum concentration was 90–100% for linear alkenes and 60–75% for branched alkenes.[27] The function of the water present may be to suppress side reactions by enabling rapid hydrolysis of the imidate to the stable amide product. However, it will also increase the solvent polarity, which is known to enhance the nucleophilicity of the nitrile through solvation and polarization effects.[28] Frequently the reaction is performed using just the nitrile and acid as solvents, but any additional diluent should be polar. Glacial acetic acid is most commonly used, although acetic anhydride, di-*n*-butyl ether, nitrobenzene and dioxane have also found favor. Nonpolar solvents such as carbon tetrachloride or hexane give poor yields,[28] and the reaction fails in the presence of methanol or ethanol.[24] Although acetic acid is the best diluent, formation of acetates can be a significant side reaction,[24,29] and in other cases dilution prevents reaction.[15]

Lewis acids such as tin(IV) chloride,[30] boron trifluoride–acetic acid[16] and boron trifluoride–etherate,[31] are also effective in promoting the Ritter reaction. In general, the original technique is more efficient, but use of Lewis acids can sometimes significantly influence the proportions of products in a mixture and has advantages when relatively sensitive substrates are present.

In reactions where rearrangement is likely, a rule of thumb is that the most stable available carbenium ion will lead to the product. Such thermodynamic control may be used deliberately to carry out complex rearrangements in high yields for suitable cases.[12] When the potential carbenium ions are of similar energy, for example in Ritter reactions of unsaturated fatty acids or esters, then mixtures of products are likely. In such cases, mass spectrometry has proved to be a particularly useful analytical technique.[32,33]

The outcome of the Ritter reaction can also be determined by kinetic control. For example, conflicting reports have appeared in the literature regarding the behavior of alcohol (**9**), the alternative products (**10**)[34] or (**11**)[35] both having been reported. These differences result from the order of addition of the reagents.[36] The amides (**10**) result if the alcohol is mixed first with the nitrile and acetic acid, the sulfuric acid being added last. In this instance (kinetic control), the initial cations are reacted to (**10**) as they are produced. Conversely, if (**9**) is mixed first with the acids, and then the nitrile is added, the products (**11**) result. In this case (thermodynamic control) carbenium ion rearrangement precedes Ritter reaction (Scheme 5). For less clear-cut cases, the use of less acidic conditions and/or lower temperature results in greater isomer selectivity, but at the cost of lower overall yields.[27]



Scheme 5

A good illustration of the interplay of reaction conditions with product formation is provided by the work of Sasaki *et al.*[37] on reactions of 1-hydroxymethyladamantane (**12**) and 3-homoadamantanol (**13**) with sulfuric acid and acetonitrile (Scheme 6). Under a variety of experimental conditions, both alcohols gave a mixture of the acetamides (**14**) and (**15**), but in quite different proportions and total conversions. A selection of these data is present in Table 1. For each entry, a mixture of the alcohol (1.2 mmol) and acetonitrile (76.5 mmol) was added to stirred sulfuric acid (1.5 ml). For the later experiments, $AlCl_3$ (0.6 g) or $BF_3–Et_2O$ (1.5 ml) were added first to the $H_2SO_4$.

The results without Lewis acid demonstrate that the homoadamantane (**14**) is the kinetic product and that the adamantane (**15**) is the thermodynamic product. Addition of Lewis acid to either alcohol decreased the yield of amides. However, while aluminum chloride increased the proportion of the kinetic product, the use of boron trifluoride etherate boosted the proportion of the thermodynamic product.

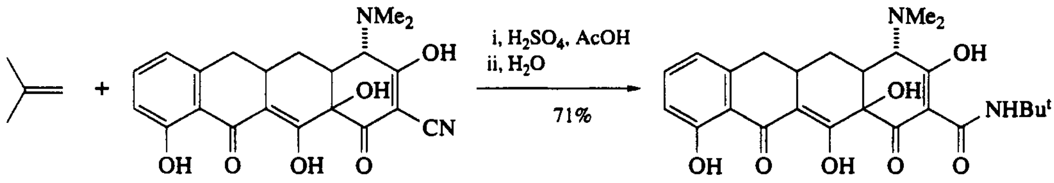
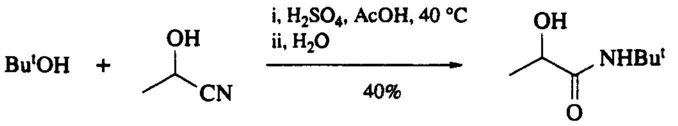
### 1.9.1.3 The Nitrile Component

In general, most compounds containing a nitrile group undergo reaction with carbenium ions.[1] Not only are hydrogen cyanide, aliphatic nitriles and aromatic nitriles all effective reagents but the process also occurs with varying degrees of efficiency for nitrile derivatives such as cyanamide, cyanogen and dicyandiamide. Nitriles bearing other functional groups undergo efficient Ritter reaction provided the materials are acid stable, a striking illustration being the tetracycline derivative (**16**; equation 2).[38] Cyanohydrins also undergo Ritter reaction without interference from the hydroxy substituent (equation 3).[39]



(2)

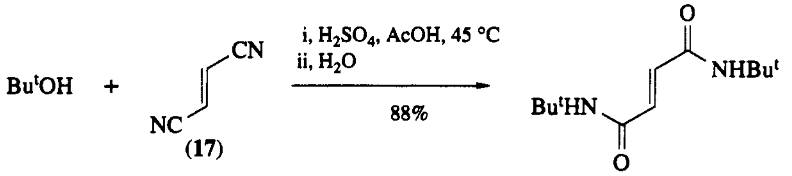
(**16**)



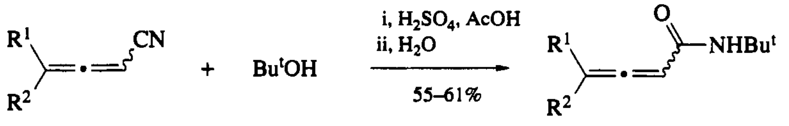
(3)

Conjugated unsaturated nitriles such as acrylonitrile[1] or fumaronitrile (**17**; equation 4)[39] are effective Ritter reagents. More recent work has shown that this is also true of conjugated allenic[40] and alkynic nitriles,[41] as shown in equation (5) and Scheme 7, respectively. Suitably functionalized propiolamides such as (**18**) are readily cyclized, allowing facile preparation of the oxazoline (**19**).[41,42]

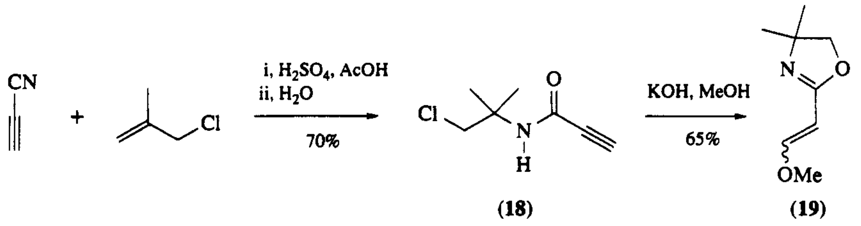
Dinitriles such as (**17**) can be used to prepare bisamides or, alternatively, can provide an excellent source of polyamides if glycol, diene,[43] or aldehyde[44,45] carbenium ion sources are utilized.



(4)

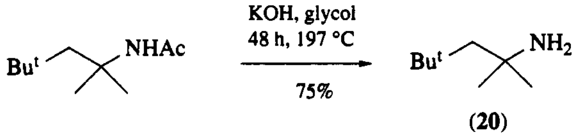


(5)

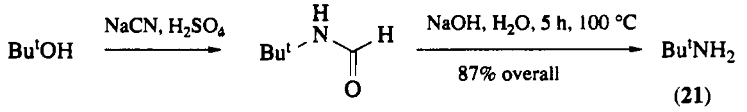


Scheme 7

Hydrogen cyanide, used either directly or generated from cyanide ion *in situ*, is an especially important nitrile source because the *N*-*t*-alkylformamide products can be readily hydrolyzed to the corresponding *N*-*t*-alkylamines.[2] Such materials, frequently of pharmacological interest,[46] could be obtained in principle by either basic or acidic hydrolysis of *N*-*t*-alkylamides. However, alkaline hydrolysis of these compounds can be surprisingly difficult to carry out in some cases.[16] For example, Ritter and Minieri[1] found that *N*-*t*-octylacetamide required prolonged reflux with 0.4 M potassium hydroxide in ethylene glycol to obtain the optimum yield of amine (**20**; equation 6). Under the same conditions, only a 27% conversion of *N*-*t*-amylacetamide was achieved. In contrast, preparation of *N*-*t*-butylamine (**21**) *via* the formamide route (Scheme 8) was possible with shorter reaction time, lower temperature, and in higher yield.[1] Although reagents such as hydrazine,[47] diisobutylaluminum hydride,[48] lithium diethylamide[49] and triethyloxonium tetrafluoroborate[50] have been used in hydrolysis of recalcitrant amides, such difficulties are best avoided by use of the formamide where possible.



(6)



Scheme 8

Although *N*-*s*-alkylamides are hydrolyzed to the corresponding amines under acidic conditions,[51] the *N*-*t*-alkyl derivatives usually undergo alkyl–nitrogen fission, producing alkene or alcohol fragments.[52] Hydrolysis of 3-acetamidohomoadamantane (**22a**) using hydrochloric acid produced a mixture of the compounds (**23a**) and (**24**), while the 1-acetamido isomer (**22b**) gave only chloride (**23b**; equation 7). The absence of amine products from these reactions[53] once again indicates the ease of $A_{AL}1$ hydrolysis[52] to the carbenium ion. If the acidic hydrolysis is conducted in the presence of ethanol, then adamantyl- and homoadamantyl-amides undergo ready deamidation. In this process, illustrated by equation (8), the ethanol acts as a hydride donor, reducing the cation to the hydrocarbon.[54]

A mechanistic limitation of the Ritter reaction is that, while *N*-alkylformamides (and thence primary amines) are readily available, further direct substitution on nitrogen is ruled out. However, simple *N*-alkylation of the formamide may be performed utilizing phase-transfer catalysis. This provides a conven-

### 1.9.1.4 The Carbenium Ion Source

In principle, any functionality capable of producing a carbenium ion under strongly acidic conditions will be able to participate in a Ritter-type reaction. Such classes of compounds include alcohols, aldehydes, alkanes, alkenes, alkyl halides, carboxylic acids, dienes, epoxides, esters, ethers, glycols, ketones, *N*-methylolamides and oximes. Consequently, an enormous number of examples is reported and only a representative selection can be presented here. A comprehensive listing of examples reported up to 1966 is provided in the review by Krimen and Cota.[12]

Despite the range of sources available, the majority of reactions described have used alcohol or alkene precursors. This reflects both the availability of such materials and their ease of reaction. Typical examples of alkene reagents are shown in equations (9),[56] (10),[30] (11)[24] and (12).[57] When two reactive groups are in close proximity in the substrate it is possible to combine transannular cyclization with Ritter reaction (equation 13).[58,59]

Tertiary alcohols tend to react without rearrangement while secondary alcohols are liable to do so, equations (14)[60] and (15),[28] as discussed in Section 1.9.1.2. Primary alcohols normally fail to react with nitriles even under severe conditions,[15] but this restriction does not apply to benzylic examples (equation 16).[29] In appropriate cases,[61] the Ritter reaction can be stereoselective (Scheme 10). Either alcohol isomer, separately or as a mixture, gave identical mixtures of the two amine products, showing that axial attack on the cation was predominant.

**Scheme 10**

In cases where more than one functional group is present in the substrate, it is usually an alcohol group which is preferred for Ritter reaction, although there are exceptions such as ricinoleic acid.[33] Examples shown here are the diisophorane derivative (**26**; equation 17)[62] and the alkynic alcohol (**27**; Scheme 11).[63] The latter compounds undergo Ritter reaction in only moderate yields because of competing Meyer–Schuster rearrangement to the unsaturated ketone in some cases. Hydrolysis of the product provides either the alkynic amine or, in the case of (**28**), the amino ketone, which undergoes selfcondensation to the dihydropyrazine (**29**). Combination of these processes into a one-pot reaction gives the latter in 54% overall yield.[64]

Similarly, *N*-methylolamides[7] (equation 18)[65,66] and substituted oximes (Scheme 12)[67,68] react specifically through their hydroxy group. Hydroxy esters afford either amido esters[69] or amido acids[70] (equation

19), depending on the conditions used. Increased substitution in the starting material results in lower yields due to competing elimination processes.[71,72] Esters of *t*-alcohols should be avoided since these may be regarded as masked *t*-carbenium ions and can participate in Ritter reactions in their own right. Thus, triphenylmethyl formate[73] or *t*-butyl acetate[20,74] produce excellent yields of *N*-*t*-alkylamides when heated with nitriles in the presence of sulfuric acid (equations 20 and 21).

Magat[75] first reported the use of *t*-alkyl halides as Ritter reaction substrates but, in general, these were less satisfactory than the use of the corresponding alcohol or alkene analogs. This process has since come into its own for polycyclic systems, where simple methods of generating bridgehead halides are often available. An early example is Stetter's conversion[76] of 1-bromoadamantane to the acetamide (**30**), there-

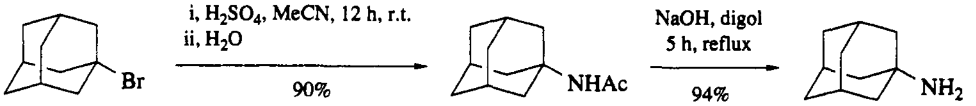
by providing a simple route to 1-aminoadamantane (**31**; Scheme 13). The discovery that (**31**) alleviates symptoms of Parkinsonism and exhibits antiviral behavior against influenza A[77] has led to considerable interest in the synthesis and testing of related polycyclic amino compounds. A number of these also show significant antiviral activity.



**(30)** **(31)**

**Scheme 13**

Saturated hydrocarbons capable of yielding a *t*-carbenium ion can participate directly in the Ritter reaction[78] provided a suitable hydride acceptor is present, or more efficiently using nitrosonium hexafluorophosphate (equation 22).[79] More recently, Inamoto[80] has described an elegant process whereby bridgehead bromination and Ritter reaction are performed in one step. This procedure is highly efficient for the functionalization of a number of tricyclic hydrocarbons, including conversion of 4-homotwistane (**32**) directly into its 3-acetamido derivative (**33**; equation 23). Although most halides used have been bromides, a recent report[81] indicates that this is not essential. Although the fluorotrishomocubane (**34a**) required more forcing conditions than its bromo analog (**34b**), the yields of amide obtained were identical (equation 24).

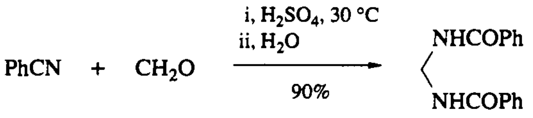
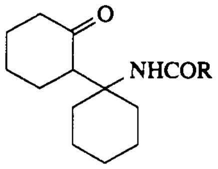
In 1876 Hepp and Spiess[3,4] reported that aldehydes react with nitriles under acidic conditions to yield geminal bisamides (equation 25). This process proceeds by a mechanistic pathway which is essentially two consecutive Ritter reactions.[26] In general, ketones do not yield similar products; however, Kozlov[82] has recently obtained a low yield of the geminal bisamide from camphor and acetonitrile. High yields of analogous products from cyclopentanone and cyclohexanone have also been reported.[83]

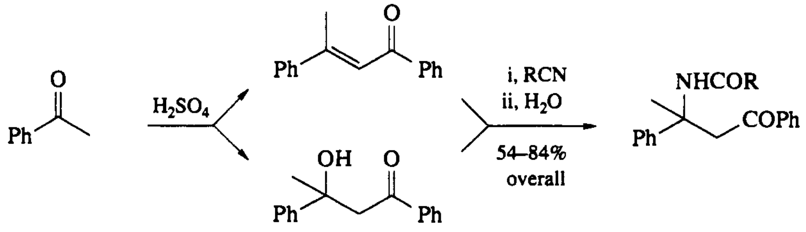


$$\mathrm{PhCN} + \mathrm{CH_2O} \xrightarrow[\text{90\%}]{\text{i, } H_2SO_4\text{, 30 °C; ii, } H_2O} \left\langle \begin{matrix}\mathrm{NHCOPh}\\ \mathrm{NHCOPh}\end{matrix}\right. \qquad (25)$$

More typical behavior of ketones is a condensation process yielding β-acylamino ketones. This process was first reported by Bruson *et al.*[84] who reacted cyclohexanone and nitriles in the presence of anhydrous aluminum chloride and obtained products now known[44] to have the structure (**35**). Such reactions were later studied in more detail by Khorlin[85] using conventional Ritter conditions. β-Acylamino ketones were obtained only from ketones capable of undergoing condensations to produce α,β-unsaturated ketones or ketols, suggesting the intermediacy of such structures in the reaction. This process is shown for acetophenone in Scheme 14. It is well established that α,β-unsaturated acids, esters and ketones yield similar products under Ritter reaction conditions.[69,70]



(**35**)



**Scheme 14**

Epoxides react efficiently with nitriles in the presence of either mineral or Lewis acids. Much of this work has been carried out on steroidal systems, which has allowed ready stereochemical analysis of the process. Such reactions yield specifically the *trans*-diaxial α-amido alcohol product, examples from the cholestanol series being shown in equations (26)[86] and (27).[87] Similar stereospecific results can also result from suitable aliphatic cases, as demonstrated by the reaction of methyl *trans*-2-epoxystearate yielding only the *erythro* isomer (**36**; equation 28).[88]

As final examples of the versatility of the Ritter reaction, bridged hemiacetals react by means of their acyclic form in solution to afford amido ketones in good yield (equation 29),[89] while halohydrins give α-amido halides, which are readily cyclized to oxazoline derivatives in an overall stereospecific process.[90]

## 1.9.2 THE INTRAMOLECULAR RITTER REACTION

The pathways by which nitrile groups can be utilized in the construction of heterocyclic systems have been reviewed by Meyers and Sircar.[14] Two of these routes constitute intramolecular variants of the Ritter reaction and, therefore, are discussed here in detail.

The more common process commences in the normal way, with addition of nitrile and carbenium ion generating a nitrilium species. However, the latter now undergoes intramolecular cyclization with a nucleophilic group in the same molecule to produce a heterocycle of structure (37; Scheme 15). The less common reaction involves initial intramolecular formation of a cyclic nitrilium ion which is then quenched by an external nucleophile, giving products of type (38).

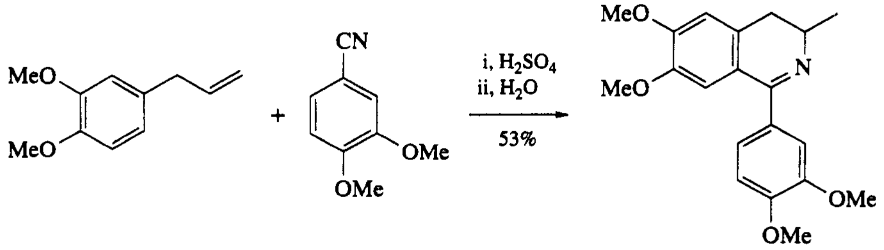
Scheme 15

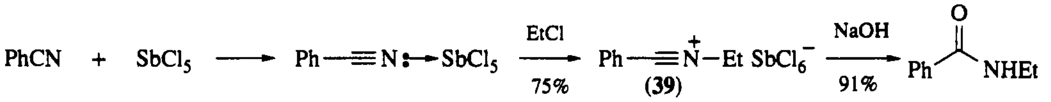
Only specific ring sizes are available from these procedures since they are constrained by the configuration of the nitrilium intermediate (Section 1.9.4), in addition to the usual factors influencing intramolecular reactions.

### 1.9.2.1 Intramolecular Cyclization of the Nitrilium Ion

In 1952, Ritter and Murphy[91] reported cases of intramolecular Ritter behavior resulting in formation of dihydroisoquinolines from reactions of methyleugenol with nitriles such as veratronitrile (equation 30). Such reactions involve nucleophilic attack by the aromatic ring on the nitrilium ion and are enhanced by the use of Lewis acids. Meerwein[23] reacted a wide range of nitrile–Lewis acid complexes with alkyl and acyl halides, obtaining nitrilium salts such as (**39**) which were readily hydrolyzed to the corresponding amide. A significant advantage of this approach, as illustrated in Scheme 16, is that this Ritter-type process is no longer restricted just to *N*-*t*-alkyl derivatives.

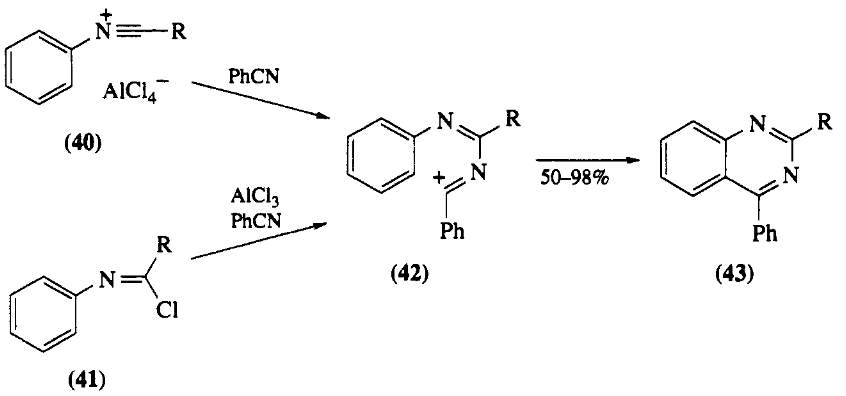


(30)

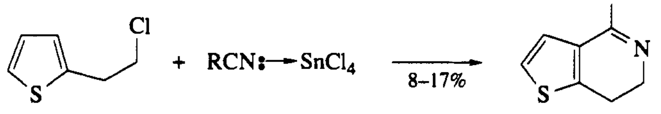


**Scheme 16**

Reaction[92] of aryl nitrilium ions (**40**) or imidoyl chlorides (**41**) with benzonitrile produced the nitrilium species (**42**), which underwent Friedel–Crafts reaction yielding the quinazoline system (**43**; Scheme 17). Generation and cyclization of nitrilium species using Friedel–Crafts reagents has since found widespread favor in heteroaromatic synthesis and such procedures have been reviewed in detail.[10,93] An illustration of its use for a nonbenzenoid aromatic system is given in equation (31).[94]



**Scheme 17**



(31)

If the internal nucleophile is an alkenic group, then 5,6-dihydropyridine (Scheme 18)[95–97] or 1-pyrroline (Scheme 19)[95] rings are produced. In a recent development[98] of the latter process, the diol (**44**) follows the same sequence to yield the carbenium ion (**45**; R = Bn). However, this now cyclizes onto the aromatic group originating from the nitrile component and produces the tetrahydrobenz[*f*]indole (**46**) in good yield, with the conventional pyrroline structure (**47**) now being only a minor product. Compound (**46**), present as a tautomeric mixture, was rapidly autoxidized to (**48**; Scheme 20). A further unusual variant of this process is the production of small quantities of the 3-azabicyclo[3.3.0]octanes (**49**) and (**50**) from Ritter reaction of 1-vinylbicyclo[2.1.1]hexane (equation 32).[99]

In 1957 Tillmanns and Ritter reported that reaction of diol (**51**) with nitriles led to dihydro-1,3-oxazine products (**52**)[100,101] instead of yielding bisamides (Scheme 21). In this process the tertiary alcohol group

is converted to a carbenium ion, whereas the secondary alcohol is retained and later acts as the nucleophile which quenches the nitrilium intermediate. Use of a hydroxy group as the internal nucleophile is the most widespread practice and invariably leads to 1,3-oxazine or oxazoline derivatives.

The dihydro-1,3-oxazine route has been extensively investigated by Meyers. Controlled reduction to the tetrahydro derivative (53), followed by hydrolysis, gave good yields of the corresponding aldehyde or deuteriated aldehyde, R—CDO (Scheme 22).[102] Further development of this concept has subsequently given rise to convenient routes to acyclic,[103] α,β-unsaturated,[104] alicyclic,[105] γ-hydroxy[106] and γ-oxo aldehydes.[106] Full synthetic details of these and other variants of the Meyers aldehyde synthesis have been published.[107]

Other processes yielding 1,3-oxazine derivatives include the reaction of chloro ketones with Lewis acids (Scheme 23)[108] and reactions of nitriles directly with malonyl chlorides (Scheme 24)[109,110] or related acid chlorides (Scheme 25).[111,112] These processes are also all believed to involve reaction of nitrilium species with an internal oxygen nucleophile.

The isolation of oxazole derivatives from Ritter-type reactions dates back to 1893, when Japp and Murray[5] reported that benzoin and sulfuric acid reacted with nitriles (equation 33). Better yields of such products are obtained from reaction of chloro ketones (**54**) with nitrile–$SnCl_4$ complexes (equation 34).[113] Likely mechanisms for these processes have been discussed by Meyers and Sircar.[14]

Japp also found that benzilic acid gave a triphenyloxazolone product with benzonitrile,[114] and later work[115,116] demonstrated that this material was (**55**; Scheme 26). The internal nucleophile in this case is the carbonyl oxygen. More recently, extensions of this type of reaction have been applied to the synthesis of sterically hindered peptides.[117] A further interesting oxazolone synthesis[118] from (**56**) involves nucleophilic attack by the nitrile on a cyclopropenium intermediate and leading ultimately to formation of the spiro derivative (**57**; Scheme 27).

The reaction of epoxides, nitriles and sulfuric acid results in generally poor yields of oxazoline derivatives, and mixtures of isomers may also result (Scheme 28).[119] These difficulties are overcome by the use of epoxy ethers (equation 35).[120,121] As shown in equation (36), oxetanes undergo analogous reactions to afford dihydro-1,3-oxazines in excellent quantities.[122]

When sulfur species act as the internal nucleophile, then thiazoline (**58**) and thiazine (**59**) products result. These processes are analogs of previously discussed oxygen examples,[95] and typical cases are

Nitrogen derivatives may also be used to trap nitrilium ions and produce heterocycles. This has been used[127] to produce the 3,4-dihydroquinazoline system (**60**) and the corresponding aromatic derivatives (**61**; Scheme 31; *cf.* Scheme 17[92]). Most examples, however, involve three-membered nitrogen species. Nitriles readily attack aziridinium salts,[128,129] *e.g.* (**62**), producing imidazoline salts (**63**; Scheme 32). Aziridines (Scheme 33) and azirines undergo similar ring expansion under Ritter conditions.[121]

Until recently, the intramolecular cyclization procedure had been used only to synthesize fused heterocyclic structures. The first report[31] of a bridged product, in 1978, involved only a minor amount (9%) of an azabicyclo[3.3.1]nonane derivative obtained from the reaction of *cis*-carveol with acetonitrile and $BF_3$–$Et_2O$. However, several effective examples are now known. These all involve reaction of the nitrilium intermediate with an internal alkenic nucleophile to yield a 1-azacyclohexene ring and a new carbenium ion which undergoes conventional, but stereospecific, Ritter reaction from the least hindered face. Such reactions are typified by formation of the multicyclic structures (**64**; equation 38)[130] and (**65**; equation 39),[131] and have considerable potential in the synthesis of complex nitrogen heterocyclic systems since suitable optically pure substrates should undergo completely stereospecific conversions. This has been confirmed by Marschoff[132] in an elegant study on (*R*)-(+)-limonene (**66**) and (1*S*)-(−)-β-pinene (**67**), which produced opposite enantiomers of the bicyclic amide (**68**; Scheme 34).

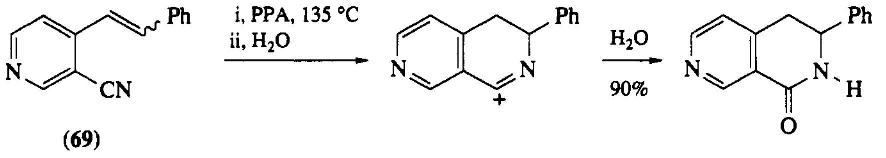
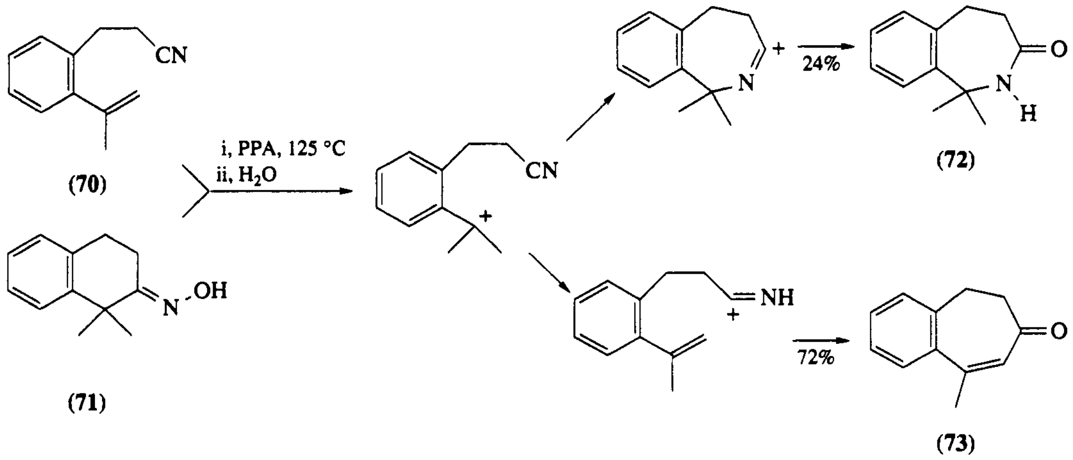
### 1.9.2.2 Intramolecular Formation of the Nitrilium Ion

Intramolecular reaction of a nitrile group and a carbenium ion can produce a cyclic nitrilium intermediate leading to Ritter-type products after reaction with an external nucleophile (Scheme 15). Geometrical considerations determine that six-membered rings are the smallest available by this mechanism. The carbenium ion is most commonly generated from an alkene, oxime, ketone or a second nitrile group.

Conversion of 3-cyano-4-stilbazole (**69**) into a tetrahydrocopyrine derivative illustrates the use of an alkenic group as the cation precursor (Scheme 35).[133] Such processes are frequently less clear-cut; for example, reaction of either the unsaturated nitrile (**70**) or oxime (**71**) resulted[134] in competitive cyclizations to the minor Ritter product (**72**) and the major Hoesch product (**73**; Scheme 36). Similar competing processes have been observed for spirocyclohexanone oximes,[135] but in other cases no cyclic products were produced at all.[136]

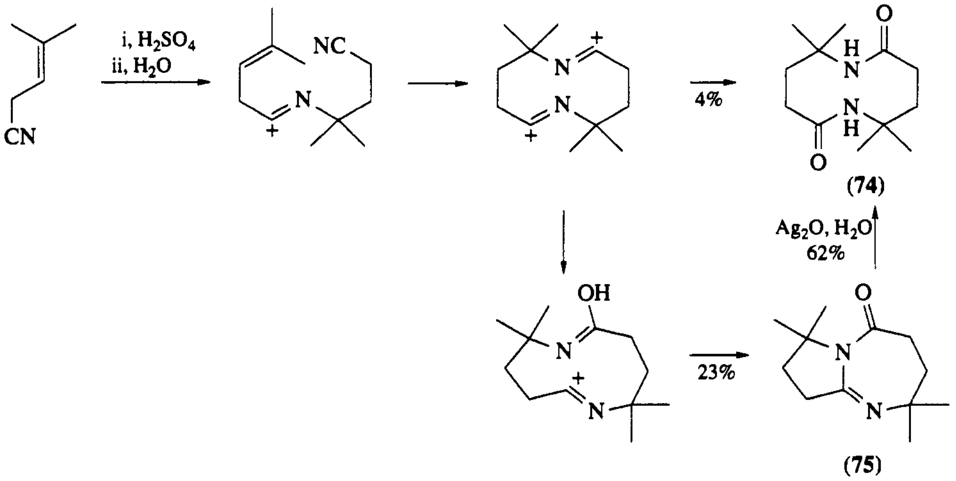


**Scheme 35**



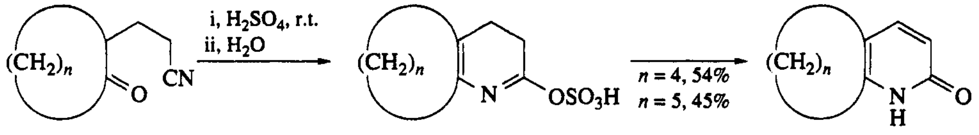
**Scheme 36**

Reports of five-membered ring formation involving this mechanism remain unauthenticated. Formation of an oxazolidinone product from Ritter reaction of cyclohexanone and cyclohexanone cyanohydrin[137] has been shown by Ducker[138] to result from an alternative pathway. Although 4-methyl-3-pentenonitrile did undergo intramolecular cyclization, this did not involve pyrrolidone formation.[139] Rather a novel dimeric process took place, leading to formation of a monocyclic (**74**) and a bicyclic (**75**) product. The latter was readily ring opened to (**74**) using silver oxide and water (Scheme 37).

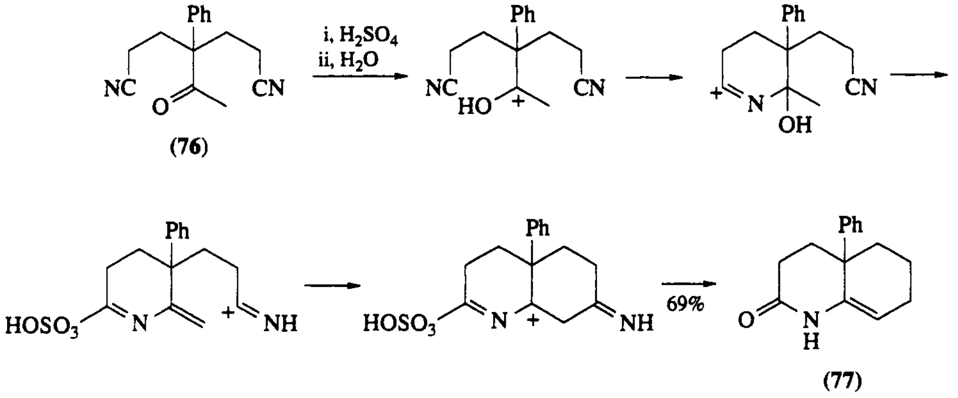


**Scheme 37**

It has been known for many years that δ-ketonitriles produce 2-pyridone derivatives under acidic conditions,[140] and such processes have been reviewed by Meyers.[14] Such reactions generally yield reduced derivatives, but in some cases (*e.g.* Scheme 38) *in situ* oxidation produces the aromatic compounds directly.[141] A further interesting example is conversion of the pimelonitrile derivative (**76**) into the bicyclic product (**77**) by means of sequential Ritter and Hoesch processes in a one-pot reaction (Scheme 39).[142]



**Scheme 38**



**Scheme 39**

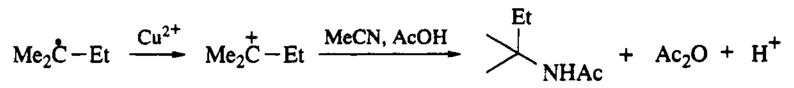
Cyclization of α,ω-dinitriles under acidic conditions has been reviewed thoroughly by Johnson and Madronero.[10] Anhydrous hydrogen halides are favored for such reactions and a wide range of five-, six- and seven-numbered heterocyclic systems are produced.

## 1.9.3 EXTENSIONS OF THE ORIGINAL REACTION

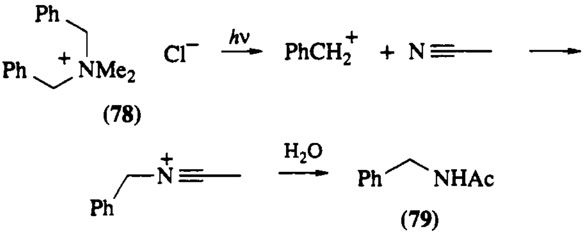
The Ritter reaction as originally reported involved generation of a carbenium ion intermediate under strongly acidic conditions, followed by reaction with the nitrile component. Not surprisingly, other means of generating the carbenium ion, or related chemical species, also result in Ritter-type processes. These newer developments have greatly added to the overall synthetic versatility of the reaction over recent years.

### 1.9.3.1 Physical Techniques

Carbenium ions generated by nonacidic routes also react with nitriles and yield amides on hydrolytic work-up. Such experiments[143] have included oxidation of free radicals (Scheme 40) using $Cu^{2+}$. Similarly, Cacace *et al.*[144] produced carbenium ions including s-$C_3H_7^+$, s-$C_4H_9^+$ and t-$C_4H_9^+$ by radiolysis, and observed reaction with nitriles and water leading to *N*-alkylamides. Ritter-type products have also been isolated from a number of organic photochemical reactions carried out in nitrile solvents. For example, photolysis of dibenzyldimethylammonium chloride (**78**) in acetonitrile resulted[145] in a mixture of products including toluene, dibenzyl, benzyl chloride and *N*-benzylacetamide (**79**). The small amounts of amide produced were postulated to result from the sequence shown in Scheme 41.

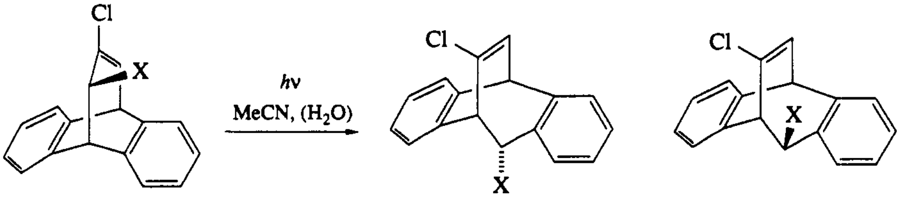


**Scheme 40**



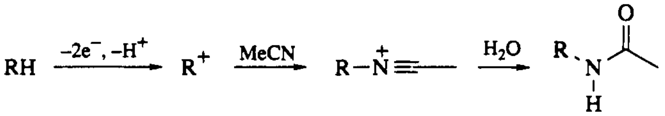
**Scheme 41**

Cristol has carried out photochemical studies on a range of cyclic halogenated substrates which yield Ritter-type products.[146] Irradiation of the dihalides (**80**) in acetonitrile normally affords a mixture of the isomeric products (**81**) and (**82**; X = halogen), plus polar material. However, when the solvent was switched to 5% aqueous acetonitrile, significant amounts of the additional products (**81**; X = OH; 15%) and (**81**; X = NHAc; 16%), plus traces of (**82**; X = NHAc) were isolated (equation 40). These new substances are believed to result from nucleophilic attack by water or acetonitrile on a ground state carbenium ion-like intermediate. A number of further, closely related reactions of this type have been described.[147-149] These photolyses consistently yield amide products but, unfortunately from the synthetic viewpoint, mixtures are often produced, and overall yields of the amides are not generally high.

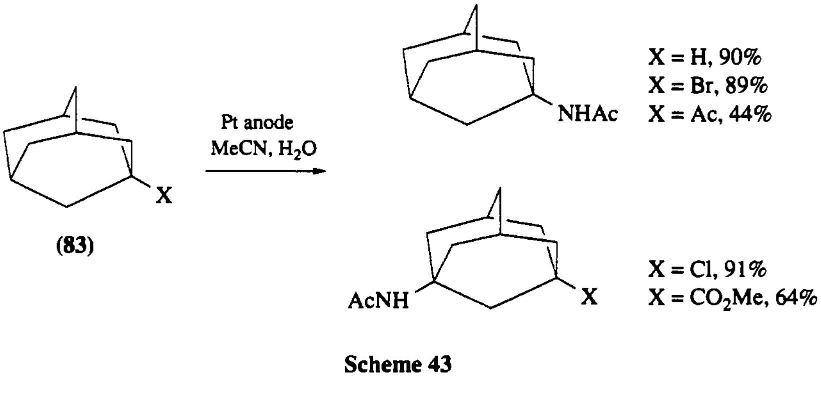


(**80**) X = Cl, Br (**81**) (**82**) (40)

The physical technique with the greatest potential for synthetic applications of Ritter-type reactions is electrochemistry. A selection only of examples is discussed here. Synthetic chemists unfamiliar with this technique will find the review by Eberson and Nyberg[150] an informative and entertaining introduction to this area. Electrochemical Ritter reactions may be performed through anodic substitution of a hydrogen by the nitrile, followed by hydrolysis of the nitrilium ion intermediate, as shown in Scheme 42. The majority of reactions investigated have been anodic acetamidations using hydrocarbons, alkyl halides, esters or ketones as the substrate. In some cases, such as reaction of the adamantane derivatives (**83**),[151] the yields of amide product are excellent (Scheme 43).



**Scheme 42**



**Scheme 43**

Anodic oxidation of *n*-alkanes in acetonitrile results in mixtures of *N*-*s*-alkylacetamides but skeletal rearrangement of the intermediate *s*-carbenium ions is not observed.[152] Aromatic compounds can undergo direct acetamidation in the ring. Thus, acetophenone, which normally undergoes electrophilic aromatic substitution at the *meta* position, affords the *o*- and *p*-acetamides (Scheme 44).[153] Anthracene is cleanly converted into the acetamide (**84**) when the reaction is performed in the presence of TFAA as water scavenger (equation 41).[154]

Generally, α-branched ketones undergo α-cleavage followed by acetamidation (equation 42),[155] while unbranched or remotely branched ketones result in substitution at remote (γ, δ and ε) positions (equation 43).[156] These modes of reaction are direct analogs of behavior in ketone photochemistry (Norrish Type I and II processes) and mass spectrometry (α-cleavage and McLafferty rearrangement). However, the electrochemical intramolecular hydrogen abstraction is much less selective, which detracts from the synthetic opportunities in being able to functionalize unactivated hydrocarbon groups at remote sites. On the other hand, acyclic esters tend to be more selective than the ketones, generally providing ω-1-substituted products (equation 44).[157]

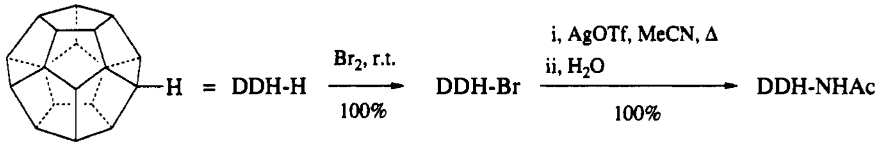
### 1.9.3.2 Metallic Reagents

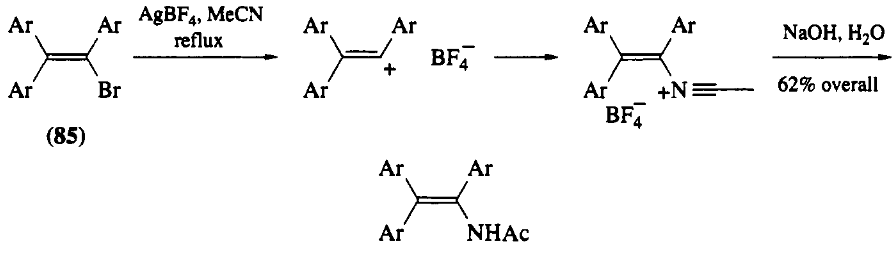
The scope of the Ritter reaction can also be extended by avoiding strong acid as the carbenium ion initiator. In at least one case it is possible to omit this reagent entirely because of the facility of $S_N1$ reaction. Thus, reflux of *t*-butyl bromide in acetonitrile or propionitrile for 24 h led to formation of *N*-*t*-butylamide products.[158] Less commonly used initiators have included cation exchange resins[159] and clayfen.[160] In this latter case, the clay-supported iron(III) nitrate is believed to give rise to nitrosonium ions, which react with the alkyl halide substrate to produce a carbenium ion. Yields of amide from this technique are generally modest (21–35%).

Earlier mention has been made of the use of Lewis acid and Friedel–Crafts reagents as initiators of carbenium ion formation. Another versatile device is to employ a metal to assist in generation of the carbenium ion. In its simplest form, addition of silver(I) ion to an alkyl halide is an excellent technique for encouraging reaction by means of the $S_N1$ pathway. This process was first applied to the Ritter reaction by Cast and Stevens,[161] but yields obtained were modest. A recent elegant application of this technique is the two-step conversion of dodecahedrane into its acetamide derivative (Scheme 45).[162]

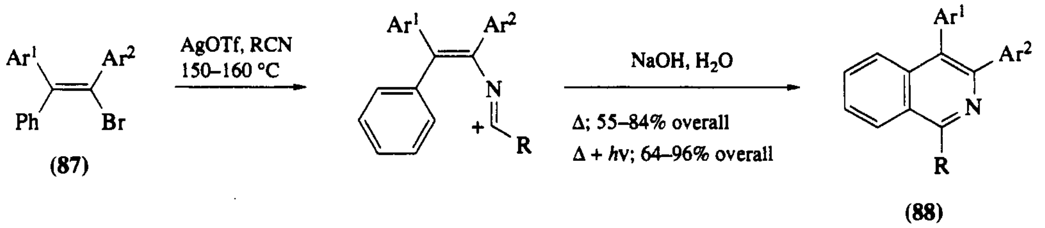


Scheme 45

Silver-assisted solvolysis of the trianisylvinyl bromide (**85**) produces a vinyl cation, which then undergoes Ritter reaction, yielding the amide (**86**; Scheme 46).[163] Other less reactive triarylvinyl bromides (**87**) required much higher temperatures for generation of the cation, and silver triflate proved a better reagent.[164] Under these conditions the intermediate nitrilium ion performed an intramolecular electrophilic aromatic substitution, producing the highly substituted isoquinolines (**88**). This conversion may also be carried out photochemically at low temperature, but in variable yield (12–77%) since the vinyl radical initially produced can carry out hydrogen abstraction reactions in competition with being oxidized to the vinyl cation. Superior yields were obtained by combining the procedures and performing sequential thermal and photochemical steps (Scheme 47).[164]

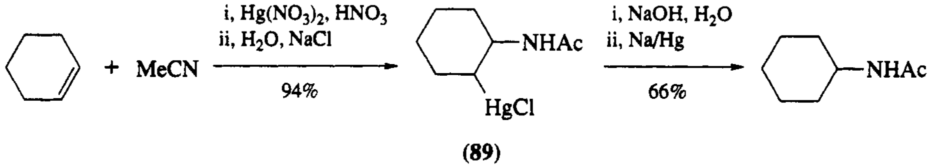


Scheme 46

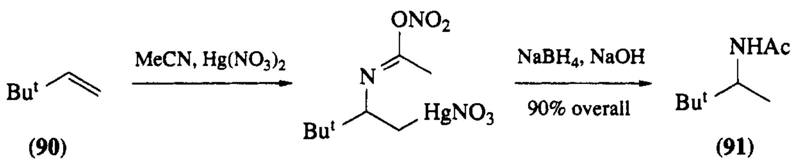


Scheme 47

Some years ago it was reported that cyclohexene reacted with mercury(II) nitrate and acetonitrile in nitric acid to give the metallic derivative (**89**), which, in turn, underwent demercuration with sodium amalgam, producing the corresponding amide (Scheme 48).[165] Later investigators[166–168] found that less severe conditions were adequate, requiring only a solution of anhydrous mercury(II) nitrate in the nitrile, and sodium borohydride, respectively. This process is analogous to the more familiar procedure developed by Brown for the hydration of alkenes using mercury(II) acetate.[169] It shares the advantage of that process in that it proceeds *via* a bridged mercurinium ion rather than a carbenium ion and, therefore, it is less prone to rearrangement. Thus, for example, the alkene (**90**) is converted into amide (**91**) in excellent yield and without formation of isomeric side products (Scheme 49).[167] Unfortunately, many alkenes fail to react in this process due to steric effects resulting from the bulky mercury reagent. When this does occur, reduction of the organomercurial intermediate produces β-amido radicals which may be coupled with electron-deficient alkenes to produce nitrogen heterocyclic products.[170,171]



**Scheme 48**



**Scheme 49**

When Delpech and Khuong-Huu[172] applied this procedure to a trisubstituted steroidal alkene, they obtained four isomeric unsaturated amide products. In crowded cases the mercuration can therefore proceed by means of an allylic oxidation pathway with concomitant rearrangement.[173] In contrast, the reaction of (–)-α-pinene (**92**) with acetonitrile and mercury(II) nitrate gave a good yield of either of the racemic 3-azabicyclo[3.3.1]nonene derivatives (**93**) or (**94**), depending on the work-up conditions used.[174] The mechanism proposed (Scheme 50) involves an intramolecular nitrilium ion cyclization similar to those discussed in Section 1.9.2. Reaction of (**94**) with aqueous formaldehyde produced the azaadamantanol (**95**) *via* another novel pathway involving loss of the C(4)-methyl group of (**94**) as acetaldehyde. Replacement of water by alternative nucleophiles allows access to a range of substituted azaadamantanes, avoiding previous multistep procedures.

This mercuration reaction has been adapted by Stevens and Kenney[175] to perform elegant stereospecific syntheses of the *Aristotelia* indole alkaloids (+)-makomakine (**97**) and (+)-aristoteline (**98**) from (–)-β-pinene and indol-3-ylacetonitrile (**96**) in only two and three steps, respectively (Scheme 51). A similar procedure from (+)-α-pinene yielded racemic hobartine (**99**) in 11% overall yield. Enantiospecificity is not observed in this reaction for the same reasons encountered during the preparations of (**93**) and (**94**).[174]

Whereas palladium(II) salts frequently react with aromatic substrates causing direct palladation, the strongly electrophilic complex (**100**) is known to interact with alkenes and induce reactions involving incipient carbenium ions. Hegedus[176] has recently demonstrated that reaction of (**100**) with a variety of alkenes can be followed by nucleophilic attack by nitriles in a palladium-assisted version of the Ritter reaction. This process is illustrated (Scheme 52) for the reaction of (**100**) with *N*-allylskatole in nitrile solvents. Initial reaction yields the σ-alkylpalladium(II) complex (**101**), which is stabilized by chelation. On reduction with sodium borohydride stereospecific reduction to the *syn*-1,2,3,4-tetrahydropyrazino[1.2-*a*]indoles (**102**) occurs, or work-up using benzylamine affords the pyrazinoindole (**103**). Alternatively, treatment of (**101**) with carbon monoxide leads to insertion, producing the acylpalladium complex (**104**) and leading to isolation of the esters (**105**).

Other examples from this study indicate that the reaction path followed by the nitrilium ion depends very much on the nature of the nucleophiles present. Thus, the allylindole (**106**) produced the imidate (**107**) through reaction of the nitrilium ion with methanol in preference to the electron-rich heterocyclic system (equation 45). In contrast, alcohol (**108**) underwent effective intramolecular cyclization (equation 46).

It is also reported that palladium(II) chloride is a suitable catalyst for Ritter reactions conducted at elevated temperature and pressure.[177]

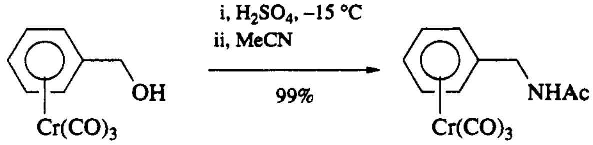
Top and Jaouen[178,179] have found that an effective means of controlling carbenium ion reactivity is to employ temporary stabilization of the ion by means of a suitable organometallic complex. Thus, while benzyl alcohol gives a 48% yield of *N*-benzylacetamide under conventional conditions,[29] the use of

($\eta^6$-benzyl alcohol)tricarbonylchromium (**109**) gave more than double that yield of the complexed acetamide (**110**; equation 47).



(**109**) (**110**) (47)

Similarly, several nitriles (such as $ClCH_2CN$ and *o*-$MeC_6H_4CN$) which tend to react poorly in the conventional reaction now reacted most efficiency (98 and 83%, respectively) with the stabilized benzyl cation. Tertiary carbenium ions were so stabilized that no Ritter reaction took place and the behavior of secondary ions depended on the particular case (Scheme 53). Complexed propargyl alcohol (**111**) was converted into the complexed acetamide (**112**) without encountering the customary acid-catalyzed rearrangement problems (equation 48).

Complexation of the $Cr(CO)_3$ group to an aromatic ring imparts a three-dimensional structure to the molecule which can be exploited in asymmetric syntheses.[179,180] Reaction of alcohol (**113**) with $Cr(CO)_6$ was followed by resolution. Complex (**114**) underwent Ritter reaction in acetonitrile yielding the complexed amide (**115**; Scheme 54). Decomplexation gave the free chiral amide whose optical purity (92%) indicated that this process took place with almost complete retention. In contrast, the indanol complex (**116**) was transformed into the Ritter product (**117**) with complete inversion of configuration (equation 49). Convincing explanations of these different stereochemical results have been provided.[179,180] These results are significant in foreshadowing future possibilities for the synthesis of chiral amides and amines by Ritter-type reactions.

### 1.9.3.3 Generation of Onium Intermediates

Electrophilic attack of alkenic groups provides a variety of cationic species available for Ritter-type reaction with nitriles, but avoiding strongly acidic conditions. Such processes involving bridged onium ions are also subject to the usual regio- and stereo-chemical factors in the ring-opening step.

Both nitronium and nitrosonium salts are effective initiators but with quite different results. Thus, propene and nitronium fluoroborate react[181] to produce the secondary α-nitrocarbenium ion which undergoes Ritter reaction with acetonitrile to yield amide (**118**). Under similar conditions, nitrosonium fluoroborate leads to heterocyclic products.[182,183] Intramolecular reaction of the nitroso and nitrilium groups, followed by prototropic shifts, affords the *N*-hydroxy imidazolium salt (**119**). This may be either neutralized to produce the *N*-oxide or reduced to the imidazole (**120**; Scheme 55).

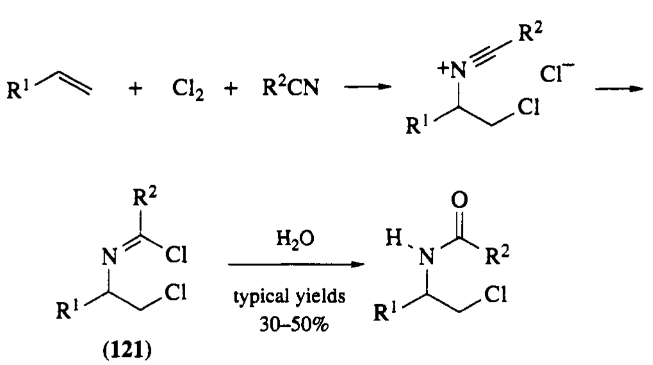
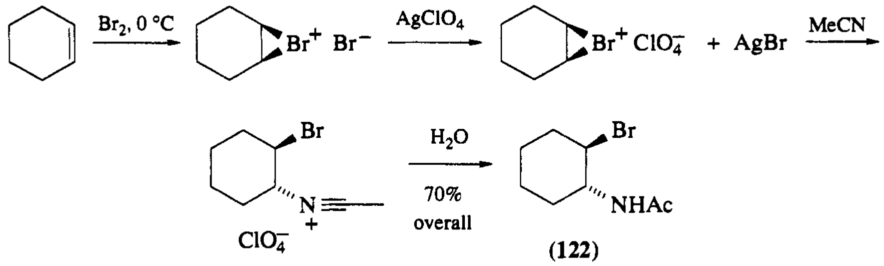
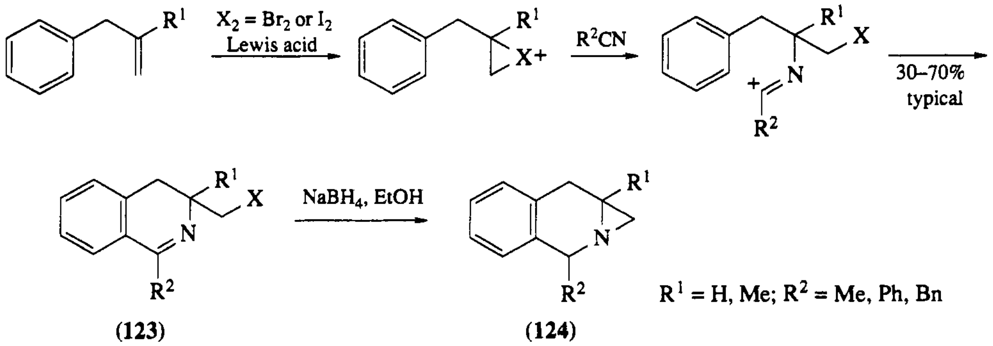
Cairns[184] demonstrated that, as initiator, chlorine provided a convenient synthesis of *N*-(2-chloroalkyl)amides (Scheme 56). In cases where the intermediate imidoyl chloride (**121**) was formed from a nitrile with no α-hydrogen atoms, then this material could be separated from the vicinal dichloride side product by distillation. Otherwise, loss of hydrogen chloride and further reaction was likely, making immediate hydrolysis to the amide desirable. One example of the use of bromine, with cyclohexene and acetonitrile, was also described, producing *N*-(2-bromocyclohexyl)acetamide (**122**) in 26% yield. Hassner[185] has since reported that this type of reaction is best carried out in the presence of silver ion, which removes bromide from solution, thus suppressing the competing formation of vicinal dibromide. Amide (**122**) was now obtained in 70% overall yield (Scheme 57). The use of alkenes, halogen and nitriles or nitrile derivatives (R—SCN, $R_2N$—CN, Cl—CN, R—OCN) has been extensively studied by Beger as a synthetic route to imidate species and derived five-membered heterocyclic systems.[186–190] This methodology can also be combined with that of the intramolecular Ritter process to synthesize 3,3-disubstituted isoquinoline derivatives (**123**) not available by Bischler–Napieralski reaction (Scheme 58).[191] Reduction affords the fused aziridines (**124**). Utilization of aziridinium species in Ritter-type processes has already been discussed (Section 1.9.2.1).[128,129]



Scheme 56



Scheme 57



$R^1$ = H, Me; $R^2$ = Me, Ph, Bn

Scheme 58

Generally, iodine azide adds to an alkene by an ionic pathway, yielding a *trans* addition product;[192] however, in a few cases nitrile reagents compete successfully with azide ion in attacking the iodonium intermediate. Thus, α-pinene was converted into tetrazole (**125**) in a one-pot reaction in near quantitative yield (Scheme 59).[193] This type of process is far from general.

More recently, these concepts have been extended to include a range of elegant amidoselenation processes. Alkenes react with benzeneselenenyl chloride and nitriles to yield β-amido phenyl selenides in excellent yield.[194,195] Oxidative elimination of the latter provides the corresponding allylic amides (Scheme 60). Since the reaction proceeds *via* an episelenonium intermediate, the amido selenides are formed with *trans* stereospecificity. However, when applied to nonsymmetrical alkenes (equation 50)[195] it only proceeds with regioselectivity.

An alternative approach[196] is to use the readily available β-hydroxy phenyl selenides as Ritter substrates. Amide formation occurs with retention of configuration, indicating that fission of the carbon–oxygen bond is assisted by the neighboring phenylseleno group (Scheme 61). Diphenyl diselenide and iodine react with 1,5-dienes to give carbocyclic products. Initial formation of the episelenonium ion is followed by intramolecular attack and subsequent Ritter reaction (Scheme 62).[197]

Vankar and Rao[198] have shown that the cationic intermediate (**126**) in the Pummerer reaction can be intercepted by nitriles producing the amido sulfides (**127**). The moderate yield of these novel products is a consequence of competition with the normal Pummerer process (Scheme 63).

## 1.9.4 RELATED PROCESSES

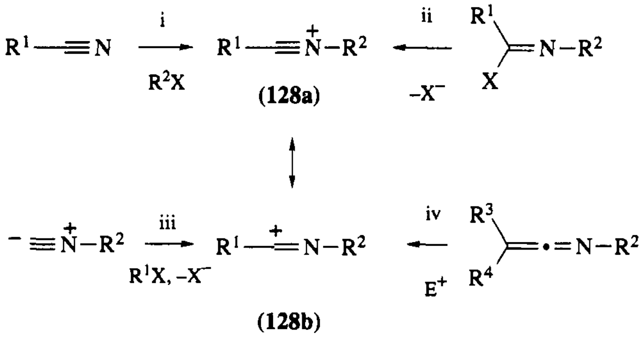
### 1.9.4.1 Relationship of Ritter and Other Reactions

Over recent years it has become clear that certain organic reactions share common intermediates and therefore have a closer relationship than previously suspected. The first step of the Ritter reaction is production of a carbenium ion, as originally reported under strongly acidic conditions, where Wagner–Meerwein rearrangements are liable to be encountered. As discussed in Section 1.9.3, alternative means of generating carbocationic species have resulted in a resurgence in Ritter-type chemistry. The recent report[199] that carbenium and nitrilium ions may be generated under mild conditions in the absence of strong electrophiles is therefore of considerable interest. Related carbenium ion reactions are those with thiocyanates yielding *N*-alkyl thiocarbamates,[200,201] and with carbon monoxide followed by hydrolysis yielding carboxylic acids (the Koch–Haaf reaction).[202] The relationship between the latter reaction and the Ritter process has been examined in detail.[203]

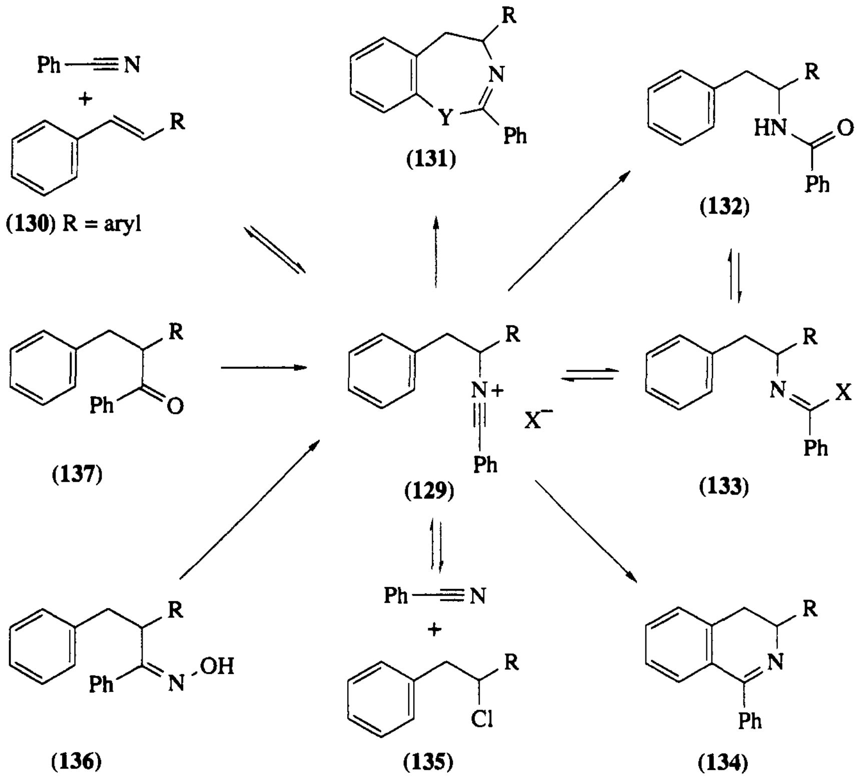
Trapping of the carbenium ion by a nitrile produces a nitrilium ion (**128**). Although such species were proposed by Hantzsch[204] in 1931, chemical syntheses did not become available for some time.[23,205] Major routes to such species now include: (i) alkylation of nitriles; (ii) reaction of imidoyl halides with Lewis acid;[206] (iii) 1,1-addition to isonitriles;[207] and (iv) reaction of ketenimines with electrophiles (Scheme 64).[208] From $^1H$, $^{13}C$ and $^{15}N$ NMR data, Olah and Kiovsky[209] concluded that nitrilium ions and protonated nitriles had a linear structure. This is supported by low temperature X-ray studies on *N*-(2,6-dimethylphenyl)acetonitrilium tetrafluoroborate where the angles $R^1$—C—N (179.2°) and C—N—$R^2$ (177.4°) were found. The C—N bond length of 1.15 A° indicated that form (**128a**) is the major contributor to the structure. However, CNDO/2 calculations revealed that, while the positive charge was spread over the entire acetonitrilium group, the carbon atom derived from the nitrile carried the most density. This may be largely due to polarization effects involving the tetrafluoroborate counterion.[210] More recently, the crystal structure of an organometallic nitrilium ion derived from *t*-butyl isocyanide has been obtained. This is significantly bent at nitrogen (169.5°), indicating a contribution from the ketenimine resonance form.[211]

Nitrilium chemistry ranges far beyond hydrolysis to an amide (Ritter reaction) or cyclization (intramolecular Ritter reaction). The generation of nitrilium triflate salts, often in high yield (72–95%),[212] has permitted detailed study of such processes.[213–215] In particular, evidence for the intermediacy of the nitrilium ion in the Beckmann rearrangement,[216,217] von Braun amide degradation[218] and Bischler–Napieralski reaction[219] has been presented. Fodor and Nagubandi[206,220,221] have done much to clarify the interplay of these previously unrecognized relationships of named reactions,[222] as illustrated in Scheme 65 for structures (**129**)–(**137**). This summary may readily be extended to include analogs of the Bischler–Napieralski reaction such as the Pictet–Gams isoquinoline synthesis and Pictet–Hubert (Morgan–Walls) phenanthridine synthesis, as well as offshoots incorporating carbenium ion and imidate chemistry.

It has been shown[208,223] that appropriately substituted nitrilium ions undergo stereospecific attack by nucleophiles to produce only the (*Z*)-isomer (**138**), *i.e.* approach of nucleophile $Y^-$ is concomitant with development of the *trans*-nitrogen lone pair (Scheme 66). While this stereospecificity may be completely general, it can only be proven for cases where addition is faster than nitrogen inversion in (**138**). The



Scheme 64



**KEY**: **Reaction name**: functional group conversion; steps involved; typical reagents

**Ritter reaction**: alkene *(etc.)* into amide, sequence **(130)** → carbenium ion → **(129)** → **(133)** → **(132)** or **(130)** → **(129)** → **(132)**; $H_2SO_4$ then $H_2O$ ($X = SO_3H$).

**Retro-Ritter reaction**: amide into alkene; reverse sequence to above; $SOCl_2$ or $P_4O_{10}$.

**Intramolecular Ritter reaction**: alkene *(etc.)* into heterocycle; sequence **(130)** → carbenium ion → **(129)** → **(131)** (where Y is a nucleophilic substituent); $H_2SO_4$ then $H_2O$.

**Bischler–Napieralski reaction**: β-phenethylamide into 3,4-dihydroisoquinoline; sequence **(132)** → **(133)** → **(129)** → **(134)**; $P_4O_{10}$ or $POCl_3$ plus Lewis acid.

**Beckmann rearrangement**; ketoxime into amide; sequence **(136)** → **(129)** → **(132)**; $PCl_5$.

**Schmidt reaction**: ketone *(etc.)* into amide; sequence **(137)** → **(129)** → **(132)**; $HN_3$ and $H_2SO_4$.

**von Braun reaction** (modified): amide into alkyl halide and nitrile; sequence **(132)** → **(133)** → **(129)** → carbenium ion → **(135)**; $PCl_5$.

**Scheme 65** Schematic summary of some major nitrilium ion reaction pathways major cases studied have therefore employed substituents ($R^2$ = OR, $NR_2$, $N{=}CR_2$ and SR) which retard inversion of the imidoyl nitrogen atom. Consequently, previously unknown materials such as *O*-acylisoamides (**139**) may be readily obtained (equation 51).[224] Such *O*-acylated products may be generated in the presence of amines as *in situ* acyl transfer reagents for peptide synthesis.[225] It seems likely that these stereochemical considerations are a major factor in the success of intramolecular Ritter cyclizations (Section 1.9.2.1).

As an extension of the amidoseleniation processes discussed previously,[194–197] imidates (the third Ritter intermediate) may be utilized as precursors for the synthesis of cyclic amides (Scheme 67)[226] and lactams (equation 52).[227] Such combination of imidate and onium ion processes has much potential for further extension of Ritter-type chemistry.

### 1.9.4.2 Isonitriles and Ritter-type processes

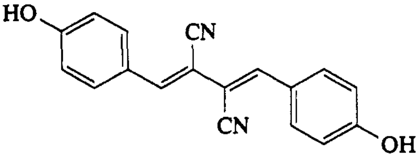
Although the isomeric nitrile (R—CN) and the isonitrile (R—NC) functional groups have structural characteristics leading to their own unique chemistry,[207,228,229] the two have much in common. They share properties such as a linear configuration, triple bonding between carbon and nitrogen, low steric demand, polarizability and similar bond strengths. Both have large and similar dipole moments, for example 3.9 D for benzonitrile and 3.5 D for phenyl isocyanide.[230] Not surprisingly, there are therefore occasions when their chemistry becomes closely related.

In valence bond terms, the isonitrile (isocyanide) group requires representation as two resonance structures (**140a**) and (**140b**), but physical properties indicate that the dipolar contribution (**140a**) is the major one. The isonitrile structure involves divalent carbon,[230] a property shared only with carbon monoxide and fulminates (R—O—NC) as isolable entities. Since the latter are notoriously reactive materials, this singles out the isonitriles as the only stable family of organic compounds which are formally divalent.

$$R-\overset{+}{N}\equiv\overset{-}{C}: \longleftrightarrow R-\ddot{N}=C:$$

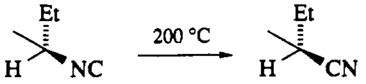
**(140a)** **(140b)**

Formerly, isonitriles were perhaps best known to many chemists through the indescribably vile odor[231] of volatile members of the series encountered during the Hofmann carbylamine test for primary amines.[232] Over recent years, however, isonitriles have come into their own as versatile synthetic reagents. Several reliable preparative methods now allow ready access to this family of substances and their remarkable chemistry.[207,233] Biological pathways to isonitriles are also known, the first such substance isolated being the antibiotic xanthocillin (**141**), isolated from *Penicillium notatum*.[234,235] Isonitrile compounds are also isolated fairly frequently from marine sources.[236]



**(141)**

It has been known for many years that on strong heating isonitriles isomerize to nitriles[237] in an exothermic, unimolecular process. For example,[238] kinetic work on *p*-tolyl isocyanide demonstrated that clean isomerization to *p*-tolunitrile took place in solution at 200 °C with an energy of activation of 154 kJ mol$^{-1}$. Cyclobutyl isocyanide underwent rearrangement to cyclobutanenitrile without ring-contraction or ring-opening side products being formed.[239] Furthermore, the homochiral isonitrile (**142**) underwent rearrangement (equation 53) with almost complete retention of configuration. It is therefore believed that the thermal isomerization process is a concerted reaction.[240] However, more recently, evidence for a competing radical process in solution reactions has been presented.[241,242] At the lower reaction temperatures normally employed in organic synthesis, these isomerization processes are not a complicating factor.



**(142)**

(53)

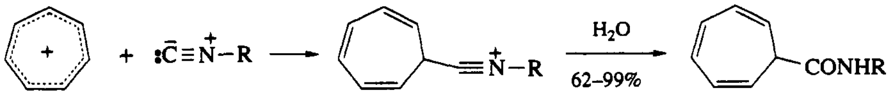
A further bridge between the chemistry of the two functional groups is formation of nitrilium ions. Nucleophilic attack on a carbenium ion by the carbon atom of an isonitrile produces a nitrilium ion (**143**) identical in all respects with that resulting from Ritter reaction (Scheme 68). In practice this process is less common than might be expected since the procedure for generating carbenium ions for Ritter reaction is through use of strong acid which would destroy the isonitrile. Thus, the tropylium ion reacts with isonitriles (Scheme 69)[243] to give a nitrilium intermediate which is hydrolyzed to the corresponding amide in traditional Ritter fashion. In a related process (Scheme 70) the benzyne precursor (**144**) reacts with cyclohexyl isocyanide to produce the amide (**145**). Here, nucleophilic attack on benzyne was followed by dehydration of the *t*-butanol solvent to yield the stable products.[244] A further interesting example[245] involves reaction of the cyclobutadiene complex (**146**) with cyclohexyl isocyanide (Scheme 71).

Acidic hydrolysis of isonitriles proceeds in two steps to the *N*-formamide and subsequently to the amine derivatives in common with nitrilium ions produced in the Ritter reaction using hydrogen

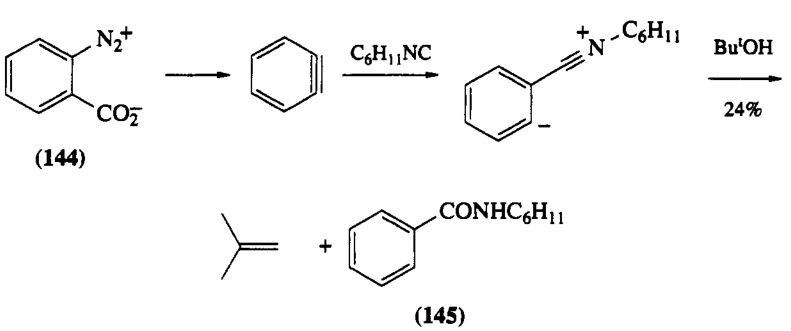
$$R^1{-}\overset{+}{N}{\equiv}\bar{C}{:} \; + \; R^{2+} \longrightarrow R^1{-}\overset{+}{N}{\equiv}{-}R^2 \longleftarrow R^{1+} + {:}N{\equiv}{-}R^2$$

**(143)**

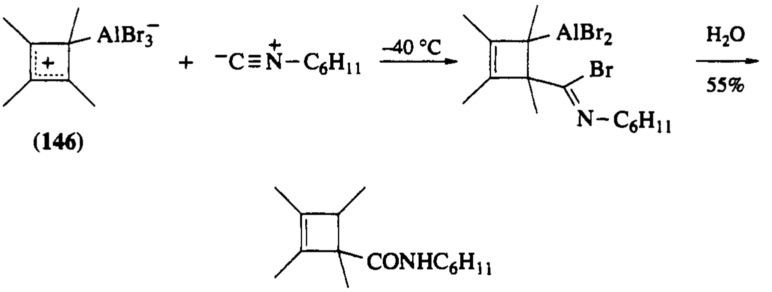
**Scheme 68**



**Scheme 69**

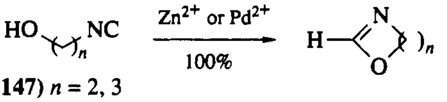


**Scheme 70**



**Scheme 71**

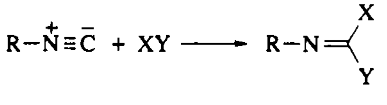
cyanide.[246] In another parallel with chemistry discussed earlier, isonitriles may also be employed in aldehyde syntheses, including production of C(1)-labeled derivatives.[247,248] Coordination of an isonitrile to a metal leads to a rich range of chemistry.[207,249] In the presence of catalytic amounts of metal ion, the hydroxyalkyl isocyanides (**147**) are cyclized in quantitative yield to the 2-oxazoline and dihydro-1,3-oxazine derivatives (equation 54).[250] This process is analogous to the intramolecular Ritter process.



(54)

A major reaction of isonitriles is α-addition of a reagent XY to the formally divalent carbon atom (equation 55), thereby yielding imidate or imidoyl products[251] and providing a further direct connection with Ritter-type reactivity. Indeed, on occasion, isonitriles have been obtained from Ritter reactions *via* such intermediates.[25,27] Recent elegant work by Livinghouse[252–254] illustrates how isonitrile chemistry is intermeshed with Ritter-type processes. Isonitriles react with acyl halides (Scheme 72) to produce keto-imidoyl halides, *e.g.* (**148**), from which the acylnitrilium ion (**149**) may be generated through reaction with silver salts. In this example, the reactive intermediate cyclizes readily and in high yield to the corresponding dihydroisoquinoline. A range of nitrogen heterocyclic systems has been synthesized using this methodology.

Isonitriles can otherwise attain tetravalent respectability by participating in cyclization reactions,[207,255] and in multicomponent condensations such as the Passerini[207] (3-component) and Ugi (4-component) reactions.[207,256] Nitrilium-type intermediates are implicated in many of these processes. These isonitrile reactions of major synthetic importance are discussed in detail elsewhere in this compendium.



$$R-\overset{+}{N}\equiv\overset{-}{C} + XY \longrightarrow R-N=C\begin{matrix}X\\Y\end{matrix} \qquad (55)$$

## 2.1.1 INTRODUCTION

Activation of the carbonyl group is the major purpose for the generation of the carboxylic acid derivatives treated in this chapter. They are of importance as intermediates in the preparation of other functionalized organic molecules. The electronic character of the substituents at the carbonyl group of the carboxylic acid increases the electrophilicity of the carbonyl C atom and, therefore, facilitates the attack by nucleophiles. The different electron-withdrawing power of the halogen atoms, the acyl group in anhydrides or the cyano group in α-ketonitriles allows a fine tuning of the electronic character of the carbonyl C atom. This can be used successfully for adapting the reactivity in the desired direction. Although acid chlorides represent the biggest number of acyl derivatives and, therefore, are used preferentially for synthetic purposes, it is sometimes of advantage to rely on other acyl compounds. α-Ketonitriles form a separate class of acid derivatives. Besides being mild acylating agents they can undergo a number of useful synthetic reactions.

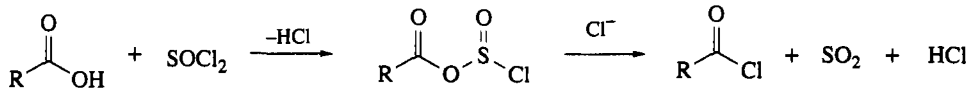
The preparation of the acid derivatives is organized according to their precursors. The synthetic method of choice in a particular case will depend on a number of factors of which the presence of other functional groups in the molecule under study is not the least important. The methods will be evaluated with respect to their scope of application. The chemistry of acid halides has been reviewed.[1] Methods of preparation are treated in Houben–Weyl[2] as well as in other reference books.[3,4] This applies also to acid anhydrides[5] and α-ketonitriles.[6]

## 2.1.2 ACID HALIDES

No explicit subdivision according to the type of halide will be made, *i.e.* the preparation of acid fluorides, chlorides, bromides and iodides will be treated simultaneously.

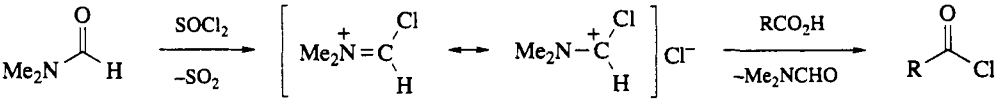
### 2.1.2.1 Acid Halides from Carboxylic Acids

The most widely used synthesis of acid chlorides is based on the reaction of a free carboxylic acid with thionyl chloride. A number of examples of this reaction can be found.[7] The mechanism seems to involve an intermediate chloro sulfite, which is transformed to the acid chloride (equation 1).[8] Polar solvents normally increase the reaction rates.[9]



(1)

The reactions can be catalyzed effectively by various additives. It has been shown that dimethylformamide constitutes an effective catalyst in many cases, the reaction being thought to proceed *via* an intermediate imidoyl chloride (equation 2).[10] The catalytic effect may be so pronounced that otherwise unreactive carboxylic acids can be transformed to their acid chlorides. An example is trichloroacetic acid which reacts only in the presence of *N*,*N*-dimethylformamide with thionyl chloride.[10] Interestingly, this reaction can also be accomplished in the presence of an alkali metal chloride.[1] Other catalysts being used include pyridine[11] and triphenylphosphine.[12] The latter converts iso- and tere-phthalic acid quantitatively to the corresponding acid dichlorides.



(2)

The nature of the catalyst seems to be important if additional functional groups are present. Thus, a complicating factor may be that double bonds in a molecule add the evolving hydrogen chloride. By using hexamethylphosphoramide and thionyl chloride at low temperature (–20 °C) this side reaction can be suppressed and in the case of acrylic acid, acryloyl chloride is formed in 80% yield.[13] The reactivity towards thionyl chloride is such that there is a correlation with the acidity of the acids: the stronger the acid the less reactive it is. A rate acceleration can be achieved in strongly polar solvents.

Phosphorus chlorides, $PCl_3$, $PCl_5$ and $POCl_3$, are common reagents for preparing acid chlorides of a variety of carboxylic acids. A comprehensive discussion of these reagents has been given by Ansell.[1] In these cases the reaction conditions, with regard to relative amount of phosphorus halide, solvent, temperature *etc.*, are important parameters for successful applications, *i.e.* tolerable yields. The often sluggish reactions with these phosphorus halides do not recommend them as reagents. Side reactions, *e.g.* oxidations at higher temperatures, and difficulties in the handling of $PCl_5$ have led to their replacement by other reagents.

Modified phosphorus halides, which allow more controlled reaction conditions, have been developed more recently. Thus 2,2,2-tribromo- and 2,2,2-trichloro-1,3,2-benzodioxaphospholes (**1a**) and (**1b**),[14–16] as well as dichloro- and dibromo-phosphoranes (**2a**) and (**2b**)[17] have been used successfully in the preparation of a number of aromatic and aliphatic acid halides. These reactions can be carried out at room temperature or slightly above and convert carboxylic acids or anhydrides in good yield to the acid halides. Also, unsaturated acids tolerate these reaction conditions. In many cases products can be isolated by distilling the acid halide directly from the reaction mixture. An advantage of these reagents is their solubility in organic solvents like diethyl ether, chloroform or benzene. Some examples are given in Table 1.

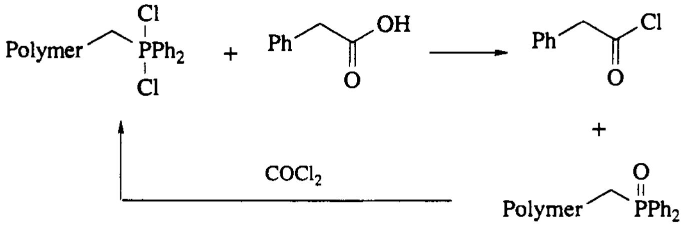
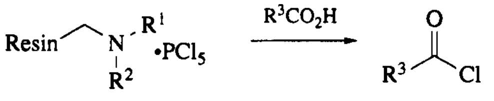
Problems of isolation which may arise for higher boiling or temperature sensitive acid halides can be circumvented by the use of polymer-bound phosphorus halides. Thus, a suspension of trisubstituted phosphine dichlorides, chemically connected to cross-linked polystyrene, reacted with carboxylic acids in methylene chloride almost quantitatively according to equation (3).[18]

Product isolation is very simple as only the solvent has to be removed after separation from the polymer. The polymer can be returned to the active chlorinating agent by reaction with carbonyl chloride. A variation of this procedure does not require polymer-bound phosphorus halide but uses Lewis acid–Lewis base complexes between anion-exchange resins, such as Amberlite IRA 93, and phosphorus pentachloride (equation 4).[19] Again, isolation of the resultant acid chloride is simple and the exhausted polymer can be regenerated for further use by simply washing it with aqueous acidic and basic solutions. Yields range from 51% for crotonic acid chloride to 86% for decanoic acid chloride.

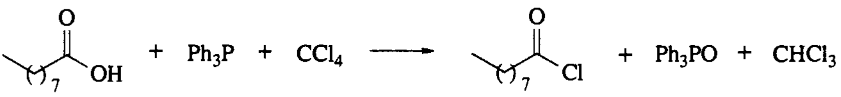


(3)



(4)

The reactions of thionyl chloride and phosphorus halides, also in their polymer-modified form, involve the formation of hydrogen halide and cannot, therefore, be applied without complications to acid sensitive compounds. The combination of triphenylphosphine and tetrachloromethane as reagent provides conditions under which, for instance, pelargonic acid can be converted to the acid chloride in good yield according to equation (5).[20] This method has been recently applied to polymer-bound triphenylphosphine.[21] Table 2 lists some examples of acids treated in this manner.



(5)

**Table 2** Conversion of Acids to Acid Chlorides by Treatment with Phosphine Resin[a] (2 equiv.) in Carbon Tetrachloride under Reflux for 4 h

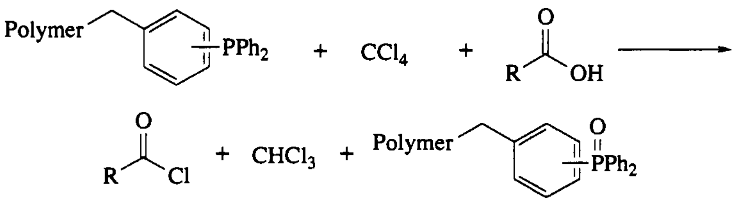
| Phenoxyacetic | 50 |
| Cinnamic | 77 |
| Benzoic | 90 |
| β-Naphthoic | 84 |
| α-Furoic | 82 |

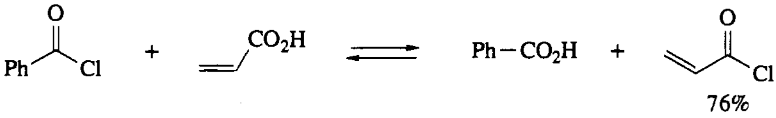
[a] 1% cross-linked polymer containing 2.50 mmol of phosphine per g.

Whereas the need to prepare the polymer might count against this technique, the commercial availability of a polymer obtained from polymerization of diphenyl-*p*-styrylphosphine would make this procedure more attractive (equation 6).[22] The process has also been tried successfully for the conversion of alcohols to alkyl chlorides. There are, however, limitations in the fact that the starting material cannot be regenerated for the reaction with carbon tetrachloride. In this respect the above mentioned reagent of Relles and Schluenz might prove superior even though it has the drawback of acidic conditions.[18]



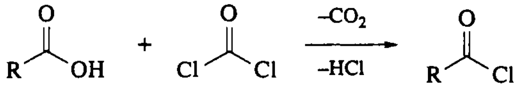
(6)

For acid-sensitive carboxylic acids it may sometimes be advantageous to use easily accessible acid halides of other carboxylic acids as halogen transfer agents. In this case an equilibrium is established between the carboxylic acid, its acid halide, the halogenating agent and its reaction product, respectively. This procedure is of particular interest if the desired product has a lower boiling point than the reagent.[23] Thus, acrylic acid can be converted to its acid chloride in 76% yield by use of benzoyl chloride as reagent (equation 7).[24] If higher boiling acid chlorides are desired then phthaloyl chloride may be a suitable reagent.[25,26] In this way maleic anhydride gives in the presence of $ZnCl_2$ *ca.* 90% fumaryl chloride. Benzenesulfonyl chloride has also been used in this context.[27] Polymer-bound aroyl chloride may be an alternative.[28]

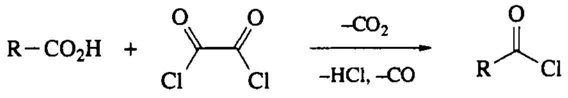


(7)

An extension of this methodology which, however, again involves the generation of hydrogen halide is the application of carbonyl chloride and oxalyl chloride (equations 8 and 9). As in the case of thionyl chloride only gaseous byproducts are formed, thus facilitating the isolation of the products. These reagents are in many cases a true alternative to the thionyl halides, sometimes giving even better yields and requiring less drastic reaction conditions. For a thorough discussion see Ansell.[1] Large scale syntheses in high yield either continuously or in batches seem to be possible by these procedures. A variety of catalysts has been applied successfully. For a list of references see Houben–Weyl.[2]



(8)



(9)

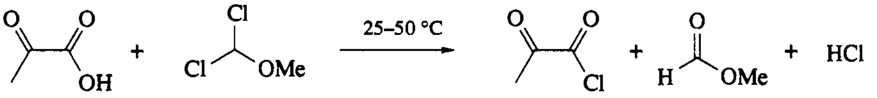
A method for converting carboxylic acids under neutral conditions to the corresponding acid chlorides is available with α-halogenated ethers as reagents. Thus it has been shown that 2-chlorodioxin can give acid chlorides of a variety of acids in good yield.[29] The method, however, has not received wide application. Instead α,α-dichloromethyl methyl ether, which can be prepared easily,[30] has replaced other α-haloethers as reagents.[31] In Table 3 some examples are listed.

**Table 3** Acid Chlorides from the Reaction of Dichloromethyl Methyl Ether[a] with Carboxylic Acids

| *Acid* | *Product* | *Yield (%)* |
|---|---|---|
| $Cl_3CCO_2H$ | $Cl_3CCOCl$ | 88 |
| $CH_2(CO_2H)_2$ | $CH_2(COCl)_2$ | 88 |
| $(CH_2CH_2CO_2H)_2$ | $(CH_2CH_2COCl)_2$ | 96 |
| $PhCO_2H$ | $PhCOCl$ | 96 |
| $PhCH_2CO_2H$ | $PhCH_2COCl$ | 92 |

[a] The reagent is used in 25% excess in the presence of 0.001 mol % $ZnCl_2$.

Sometimes the addition of a small amount of $ZnCl_2$ as a catalyst is recommended, *e.g.* succinic acid is transformed to the dichloride only in the presence of this catalyst. It has to be noticed, however, that under these conditions hydrogen chloride is evolved and, therefore, acid sensitive compounds cannot be taken. *N*-acylamino acid chlorides[32] and chlorides of fully acetylated sugar acids[33] are also obtainable in yields of 70% or more. Whereas most reagents seem to be unsuited to the preparation of acid halides of α-keto acids, dichloromethyl methyl ether is successful in this reaction (equation 10).[34] Pyruvyl chloride can now be made in *ca.* 50% yield.[35] In some examples the corresponding α,α-dibromomethyl methyl ether has also been tested.[36]



(10)

There are as shown a number of reagents for the preparation of acid chlorides; acid bromides are also produced by similar reactions, *e.g.* with thionyl bromide.[37] A general approach to obtain acid halides of fluorine, chlorine, bromine and iodine has been described by Ghosez *et al.* (equation 11).[38] 1-Dimethylamino-1-chloro-2-methylpropene, which is accessible from *N*,*N*-dimethylisobutyroamide,[39] is a generally applicable reagent for this purpose. The other halo derivatives can be formed by halogen exchange. Under very mild conditions, *i.e.* at room temperature or below in dichloromethane as solvent, the acid halides are obtained in high yield (Table 4). No hydrogen halide is evolved, so acid labile compounds

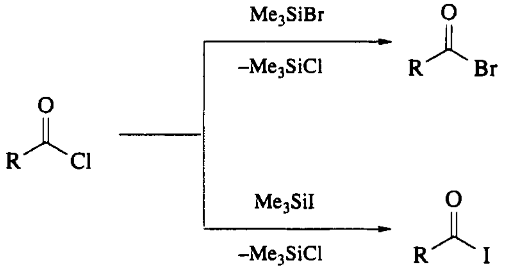
can also be subjected to this reaction. Also thermally unstable acid halides such as formyl chloride or formyl iodide can be made due to the high reactivity of the halogenating agent, which permits the use of temperatures as low as –60 °C.

Some special procedures for the preparation of acid fluorides from carboxylic acids will be added at this point. Several reagents have been suggested recently. Olah proposed the adduct of pyridine and $SeF_4$.[40] In halogenated solvents at room temperature the acid fluorides are normally isolated in yields greater than 80%. Similar good results were reported for cyanuric fluoride, which is prepared from cyanuric chloride with hydrogen fluoride.[41] The reactions are carried out in acetonitrile in the presence of pyridine. Double bonds, triple bonds and hydroxy groups are tolerated under these conditions. These new methods seem to be superior to sulfur tetrafluoride for the generation of acid fluorides.[42]

### 2.1.2.2 Acid Halides from Acid Halides by Transformation

As a synthetic approach this reaction is valuable for the generation of acid bromides, acid iodides and acid fluorides. The readily accessible acid chlorides are a convenient starting material. Thus, it is possible to react acid chlorides with hydrogen fluoride, hydrogen bromide or hydrogen iodide to obtain the corresponding acid halides.[43]

More recent approaches which avoid acidic conditions are based on the application of trimethylsilyl bromide or iodide (equation 12).[44] With aliphatic acid halides a high reactivity (often the reaction is exothermic) is observed. The isolation of the products can be effected immediately after the addition of trimethylsilyl halide is complete. With aromatic halides heating is sometimes required. Easy work-up is possible, because only the low boiling trimethylsilyl chloride has to be removed before the product is isolated by distillation. Table 5 gives some examples.



(12)

**Table 5** Acid Bromides and Acid Iodides from Acid Chlorides *via* Reaction with Trimethylsilyl bromide or Iodide

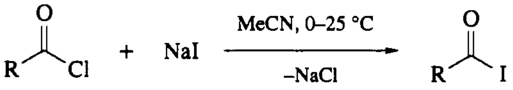
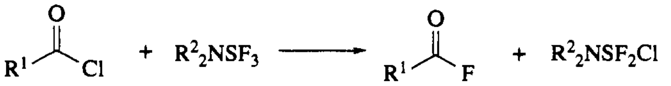
| PhCOBr | 79 | $Pr^nCOI$ | 86 |
| $(COBr)_2$ | 85 | PhCOI | 83 |
| $(H_2CCOBr)_2$ | 78 | | |

Another versatile pathway to acid iodides was described by Hoffmann (equation 13).[45] Aliphatic and aromatic acid iodides are prepared in high yields from acid chlorides by reaction with sodium iodide in acetonitrile. A large number of alkanoyl, alkenoyl and aroyl iodides can be prepared in good yields from the corresponding acid chlorides. In the same way it was possible for the first time to obtain diiodides from aliphatic and aromatic dicarboxylic acids.[46] The conversion of acid chlorides to iodides by sodium iodide had been known before;[47,48] the reaction conditions proposed by Hoffmann, however, are milder and the yields are higher.

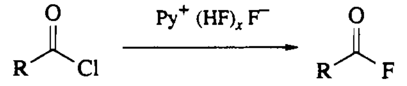


(13)

The transhalogenation reaction has been applied widely to the preparation of acid fluorides.[1] Newer developments include the use of dialkylaminotrifluorosulfonate as reagent (equation 14).[49] This compound not only converts a variety of organic acid chlorides to acid fluorides but is also able to produce thionyl fluoride from thionyl chloride as well as other fluorides of inorganic acids. A mixture of pyridine (30%) and hydrogen fluoride (70%) has been proposed as a replacement for hydrogen fluoride itself, because it is a stabilized, less volatile form of HF (equation 15). This is a versatile reagent which among many other fluorinations can produce acid fluorides in excellent yields.[50]



(14)



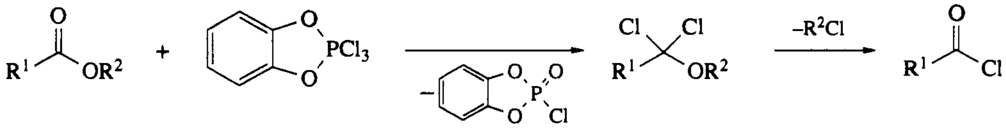
(15)

### 2.1.2.3 Acid Halides from Acid Anhydrides

Acid anhydrides as activated derivatives of carboxylic acids have found little attention for the preparation of acid halides. Their use can be justified if they are obtained from other sources than from carboxylic acids, *e.g.* phthalic anhydride from the oxidation of naphthalene or *o*-xylene. It is, therefore, no surprise that there exist patents to convert phthalic anhydride to phthalic acid dichloride with carbonyl dichloride in the presence of catalysts.[2,51–53] However, there are some methods available; thus α,α-dichloromethyl methyl ether will convert acid anhydrides to acid chlorides[31] and brenzcatechyl phosphorus tribromide will also achieve this transformation.[36] Fluorides may be prepared similarly with the pyridine/HF mixture of Olah.[50]

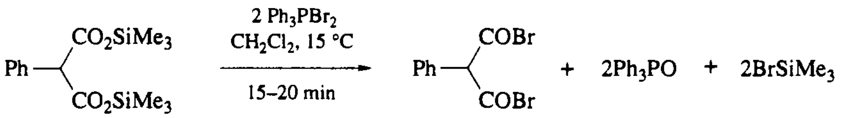
### 2.1.2.4 Acid Halides from Carboxylic Acid Esters

If carboxylic acid esters are readily available, they provide a convenient basis for the preparation of acid halides. Modified phosphorus halides, like 2,2,2-trichloro-1,3,2-benzodioxaphosphole can be applied successfully.[15] This reagent forms first a 1,1-dichloroalkyl ether, which decomposes to the acid chloride (equation 16). The reaction conditions are rather drastic. For instance *n*-butyl benzoate has to be heated for 4 h at 180 °C in order to get a 90% yield of benzoyl chloride. The only stable and isolable 1,1-dichloro ether is α,α-dichloromethyl methyl ether, which, as described above, is used as a mild reagent for the conversion of carboxylic acids to their chlorides. Similarly severe conditions are required if the chlorine or bromine adduct of triphenylphosphine is selected.[54,55] This reaction may be catalyzed by $BF_3$. It has been applied successfully to unsaturated esters and to the cleavage of lactones.



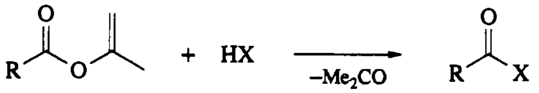
(16)

Neutral conditions are also realized if trimethylsilyl esters are reacted with dibromotriphenylphosphine.[56] This reaction, as shown in equation (17), can also be applied to sterically hindered trialkylsilyl esters.[57]

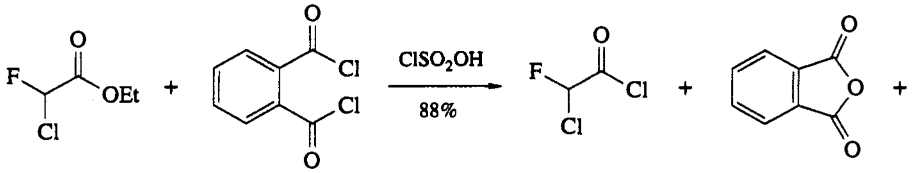


(17)

A general route to acid fluorides, chlorides, bromides and iodides is provided by the reaction of enol esters, such as isopropenyl esters, with the appropriate hydrogen halide (equation 18).[58,59] Phthalic acid dichloride in the presence of chlorosulfonic acid has been proposed as a reagent for the conversion of carboxylic esters to acid chlorides in high yield, as is shown in equation (19) for the cleavage of the ethyl ester of chlorofluoroacetic acid.[60]



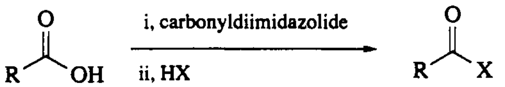
(18)



(19)

## 2.1.2.5 Acid Halides from Acyl Amides and Hydrazides

Staab introduced azolides as versatile reagents in organic synthesis.[61] The reaction of carbonyldiimidazolide with carboxylic acids produces imidazolides under mild conditions which can be converted by the action of hydrogen halides to acid halides in high yield (equation 20). The method does not even require the isolation of the imidazolides, but can be carried out as a one-pot synthesis.[62] The possibility of carrying out this reaction at low temperatures allows the preparation of temperature sensitive compounds. Formyl chloride, which decomposes at −40 °C, has been prepared in this way.



(20)

Other possibilities include the reaction of hydrazides with hydrogen chloride in nitromethane or methylene chloride.[63] Also thionyl chloride or sulfuryl chloride will produce acid chlorides from hydrazides,[64] although these reactions seem to be of limited scope.

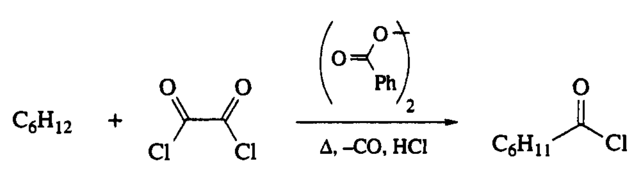
## 2.1.2.6 Acid Halides from Aldehydes

Aldehydes were among the first compounds to be converted to acid chlorides. Thus, Liebig and Woehler reported the formation of benzoyl chloride from benzaldehyde.[65] A discussion of acid halide syntheses starting from aldehydes is given in ref. 1. Most of these reactions seem to be of free radical character, carried out using reagents like *t*-butyl hypochlorite, *N*-chlorosuccinimide or *N*-bromosuccinimide. In special cases where aldehydes are readily available and where functional groups prevent the application of other methods, these reagents might constitute an alternative for the preparation of acid halides. The use of *N*-bromosuccinimide for the direct oxidation of aldehydes to acid bromides has been taken up recently.[66] Iodobenzene dichloride has also been described as a reagent for producing acid halides directly from aldehydes.[67]

## 2.1.2.7 Acid Halides by Introduction of a Halocarbonyl Group

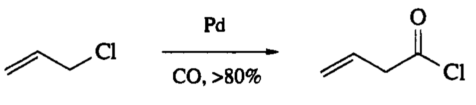
The conversion of an organic compound to an acid halide by introduction of a halocarbonyl group directly is an attractive synthetic possibility. Thus, acid halides can be obtained if hydrocarbons are reacted with oxalyl chloride in the presence of free radical initiators like dibenzoyl peroxide. Obviously, this will not be a very selective procedure and only highly symmetrical compounds with preferentially one type of CH bond will lead to acceptable selectivity and yield. Kharash showed that cyclohexane can give cyclohexanecarboxylic acid chloride in 65% yield according to equation (21).[68] Higher selectivity can be expected if functionalized compounds render one kind of CH bond particularly reactive towards free radical abstraction. Substituted malonic acid dibromides are formed in this way by reaction of acid bromides with oxalyl bromide in yields ranging from 40 to 70%.[69] A radical chain reaction in tetrachloromethane in the presence of carbon monoxide is another alternative.[70,71]

In principle the possibility of introducing a halocarbonyl into aromatic compounds with carbonyl dichloride in the presence of Lewis acids exists. In practice it is difficult to stop the reaction after the first electrophilic substitution, because the reaction products themselves can react further to give ketones.[72] However, there are exceptions. Thiophene reacts with phosgene in the presence of aluminum trichloride to give 2-chlorocarbonylthiophene almost quantitatively.[73]



(21)

An attractive pathway with a lot of potential uses the transition metal mediated reaction of organic halides with carbon monoxide.[74–76] Suitable substrates are organic halides capable of oxidative addition to low-valent transition metal compounds. Insertion of carbon monoxide and reductive elimination of an acid halide will complete the catalytic cycle. In this way it was shown that allyl chloride yields butenoic acid chloride in >80% yield according to equation (22).[77,78] As well as palladium, rhodium and iridium also act catalytically.[2] It is of no surprise that allylic halides, benzylic halides and aryl halides in particular are readily converted to acid halides. Simple aliphatic halides undergo the oxidative addition step more slowly and, if they carry hydrogen atoms on an $sp^3$ hybridized C atom in the β-position to the halogen atom, may give alkenes *via* β-hydrogen elimination. Alkenes can also be converted to acid halides with carbon monoxide in the presence of transition metal catalysts in solvents such as methylene chloride or tetrachloromethane.[79]



(22)

### 2.1.2.8 Miscellaneous Methods of Preparation of Acid Halides

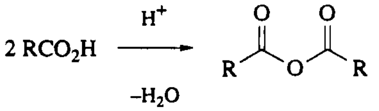
There are a number of specialized methods for the preparation of acid halides which, however, do not seem to have general applicability. For a summary see ref. 1.

## 2.1.3 ACID ANHYDRIDES AND MIXED ANHYDRIDES

Acid anhydrides play a similar role in organic chemistry to acid halides. The enhanced electrophilic character of the carbonyl groups renders them valuable intermediates in organic syntheses. Several general approaches exist for their preparation and depending on the availability of the starting material or the presence of sensitive functional groups one or the other procedure may be the method of choice for their generation.[80]

### 2.1.3.1 Acid Anhydrides from Carboxylic Acids by Dehydration

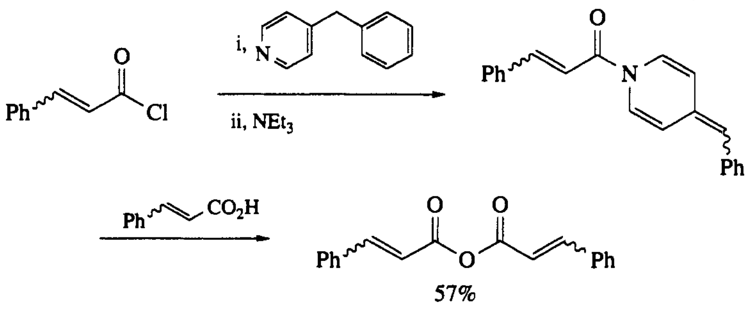
The most general procedure for the preparation of acid anhydrides starts from free carboxylic acids which are activated by suitable reagents in order to make the overall bimolecular dehydration process feasible under moderately mild conditions. Thermal dehydration, in principle the simplest method (equation 23), is only of limited preparative value giving the acid anhydride only in low yield.[81,82] Even in special cases, where dicarboxylic acids may form five- or six-membered rings, anhydride formation requires dehydration agents. In the simplest case concentrated sulfuric acid may be applied.[83] For some examples see ref. 80. The advantage of an intramolecular dehydration, which is favored entropically, is lost in longer chain α,ω-dicarboxylic acids where normally intermolecular reactions with the formation of polymers is the result. In general more specific reagents have to be found to effect the elimination of water from two molecules of carboxylic acid to form an acid anhydride.



(23)

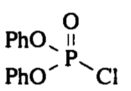
If thionyl chloride is used for activation, it is possible to react the carboxylic acid in the presence of 0.5 equiv. of the reagent. The acid halide formed initially reacts further with free carboxylic acid under elimination of hydrogen chloride. Two modes of operation are possible: either the free acid is boiled under reflux in a solvent in the presence of thionyl chloride[84] or the reaction is carried out in the presence of pyridine as base.[85] Pyridine not only traps the liberated hydrogen chloride but takes part in the mechanism of formation of the acid anhydride, allowing milder conditions than in its absence. Mostly simple aliphatic carboxylic acids have been converted to their anhydrides by this method. The just described processes lead to acid anhydrides *via* the reaction of acid halides formed *in situ* with free carboxylic acid. In some cases, and in particular if mixed anhydrides are desired, it is advantageous to react isolated acid halides with carboxylic acids. This reaction is either carried out in inert solvents in the presence of bases such as pyridine[86] (Schotten–Baumann reaction) or in aqueous medium in the presence of sodium bicarbonate.[87] Acid anhydrides of higher boiling long chain aliphatic acids can be generated by simply heating an approximate 1:1 mixture of acid and acid halide and recrystallizing the product.[88]

An acyl transfer agent which can be used for the synthesis of acid anhydrides is obtained from the reaction of an acid chloride with 4-benzylpyridine (equation 24).[89] In this way benzoic acid anhydride and cinnamic acid anhydride were obtained in 72% and 57% yields, respectively. As the intermediate, 1-acyl-4-benzylidene-1,4-dihydropyridines, can be isolated, this procedure should be well suited for the preparation of mixed anhydrides. Mixed aromatic and aliphatic anhydrides can be prepared with 2-benzoylthio-1-methylpyridinium chloride and salts of carboxylic acids.[90] These reactions are carried out in aqueous solution. They make use of the high reactivity of esters of thiocarboxylic esters towards nucleophiles. The mixed anhydrides of benzoic acid with 3-phenylpropanoic acid, phenoxyacetic acid, isobutyric acid, *p*-toluic acid and cinnamic acid were formed in 82, 79, 61, 91 and 66% yields, respectively.

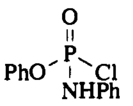


(24)

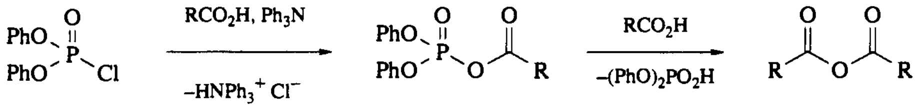
Activation of carboxylic acids by phosphorus acid halides in the form of different derivatives (3–7) has been used extensively in more recent years. These methods have been tested not only for saturated aliphatic or aromatic carboxylic acids but also for functionalized derivatives. In Table 6 some examples are collected where (3) and (4) were applied successfully.[91] The reactions are carried out at room temperature in acetone or dichloromethane by treatment of the carboxylic acid with 1 equiv. of triethylamine or *N*-ethylpiperidine and 0.5 equiv. of the reagent (equation 25). The anhydrides are either collected by filtration or recovered by evaporation of the solvent after washing with water.



(3)



(4)



(25)

**Table 6** Symmetrical Carboxylic Acid Anhydrides from Carboxylic Acids and Reagents (3) and (4)

| *$RCO_2H$* | *Reagent* | *Yield (%)* |

A still greater number of acid anhydrides has been prepared with reagent (**5**), which is obtained easily from phosphorus pentachloride.[92] The reactions take place at room temperature in the presence of a tertiary base. Selected examples are given in Table 7. Anhydride formation was also reported with (**6**) and (**7**).[93] Dihalide derivatives of phosphorus oxychloride have been tested as well.[94,95]

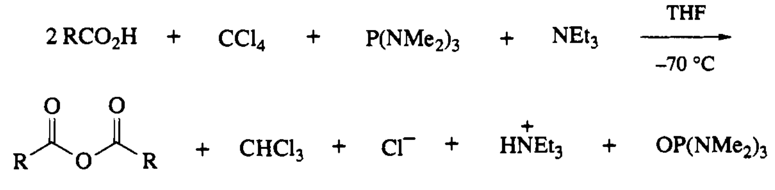
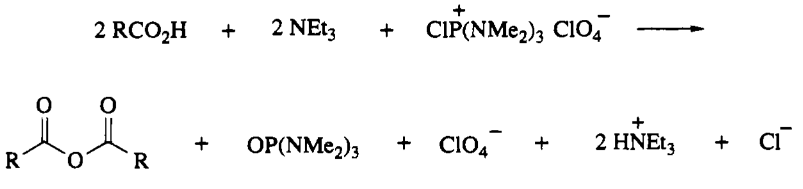
A procedure which converts carboxylic acids under very mild conditions to acid anhydrides was discovered in the reaction of 2 equiv. of acid with carbon tetrachloride in the presence of 1 equiv. of hexamethylphosphoramide and 1 equiv. of triethylamine in THF at –70 °C (equation 26). The anhydride of cyclopropanecarboxylic acid is, for example, formed in 76% yield.[96] The reaction can be modified in the sense that preformed chlorotrisdimethylaminophosphonium perchlorate is used as reagent. At room temperature acids are transformed into anhydrides in very good yield according to equation (27).[97] The latter reagent can be applied successfully to the coupling of amino acids to form peptides.

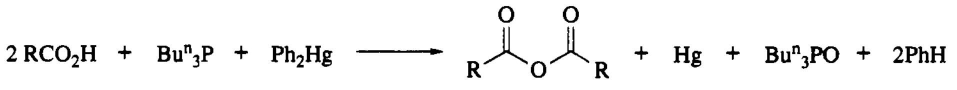


$$2\,RCO_2H + CCl_4 + P(NMe_2)_3 + NEt_3 \xrightarrow[-70\ ^\circ C]{THF} RC(O)OC(O)R + CHCl_3 + Cl^- + H\overset{+}{N}Et_3 + OP(NMe_2)_3 \qquad (26)$$

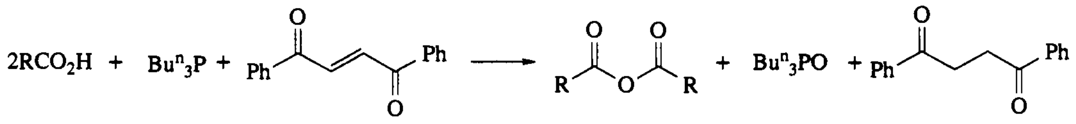


$$2\,RCO_2H + 2\,NEt_3 + Cl\overset{+}{P}(NMe_2)_3\,ClO_4^- \longrightarrow RC(O)OC(O)R + OP(NMe_2)_3 + ClO_4^- + 2\,H\overset{+}{N}Et_3 + Cl^- \qquad (27)$$

On the basis of organomercury compounds Mukaiyama introduced a method for the production of acid anhydrides. Thus the reaction of diphenylmercury with carboxylic acids in the presence of tri-*n*-butylphosphine leads to anhydrides of aliphatic and aromatic carboxylic acids in yields of *ca.* 80% (equation 28).[98] The reaction is regarded as proceeding through initial formation of phenylmercury(II) carboxylates. Oxidation–reduction reactions with tri-*n*-butylphosphine as reducing agent and electron deficient alkenes as oxidizing agents were also proposed as a means of obtaining acid anhydrides from carboxylic acids (equation 29).[99] *trans*-Dibenzoylethylene as electron acceptor in this reaction allows the preparation of aliphatic acid anhydrides in good yield. Quinoidal systems[100] or azodicarboxylates[101] can also assume the role of the electron acceptor.

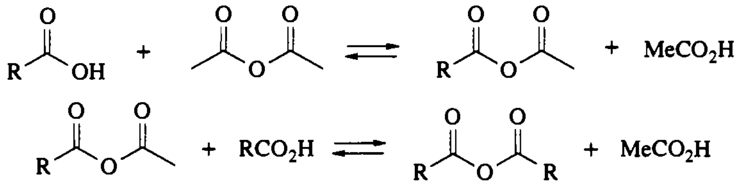


(28)



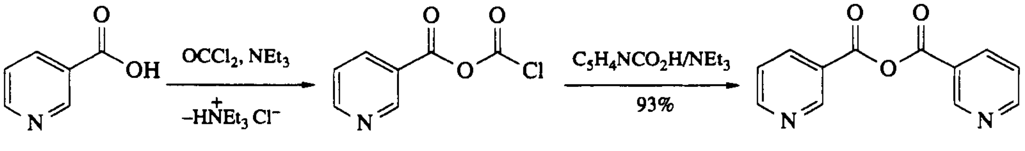
(29)

One of the most widely applied methods of synthesis for acid anhydrides consists of the reaction of a free carboxylic acid with an acid anhydride, in particular with acetic anhydride as dehydrating agent.[102,103] The process (equation 30) involves the intermediate formation of a mixed anhydride and is normally driven to completion by distilling off acetic acid. Acetic anhydride is used as solvent. The method can be used in all those cases where the desired product has a higher boiling point than acetic acid. The yields are good to excellent. Acid halides can be considered as mixed anhydrides of an organic and an inorganic acid. It is therefore obvious that they may be chosen as activated derivatives of carboxylic acids from which acid anhydrides can be formed conveniently. Both aliphatic and aromatic acid anhydrides are accessible by this approach. The reaction is favorably carried out in the presence of pyridine, which forms an acylpyridinium salt with the acid halide. The yields are >80%.[104]

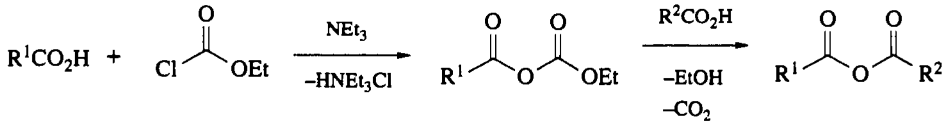


(30)

Carbonyl dichloride can be taken similarly to form acid anhydrides (equation 31). *Via* a mixed anhydride and in the presence of triethylamine, it is possible to prepare symmetrical anhydrides in high yield.[105,106] A variation provides ethyl chloroformate as reagent.[107,108] In a first step the carboxylic acid is ethoxycarbonylated in the presence of triethylamine and then reacted with free carboxylic acid to form the acid anhydride (equation 32). As the intermediate can be isolated, this is a good method of forming mixed anhydrides.[109] In addition it seems to be particularly suitable for functionalized carboxylic acids such as hydroxy acids.[110] Polymer-bound chloroformates may be advantageous in some cases.[111,112]

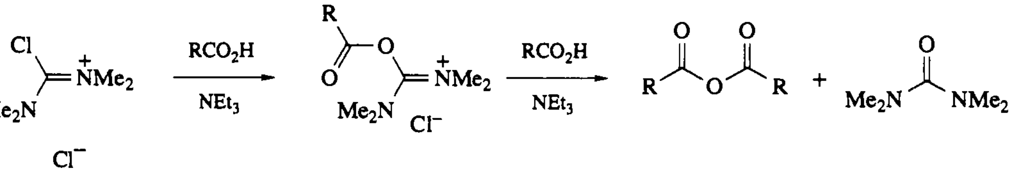


(31)



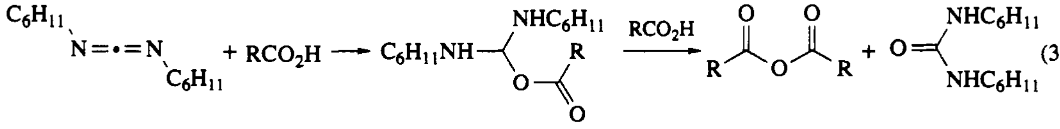
(32)

An analogous methodology can be seen in the proposal to use chloroformamidinium salts as dehydrating agents.[113] *N,N,N′,N′*-Tetramethylchloroformamidinium chloride, used as the condensation agent, is easily available by the reaction of *N,N,N′,N′*-tetramethylurea and oxalyl dichloride. The reaction of carboxylic acids (equation 33) can be achieved at –30 °C in the presence of triethylamine. Thus, for instance, 2-furoic acid, cinnamic acid and crotonic acid yield the anhydrides in 84%, 83% and 83%, respectively.



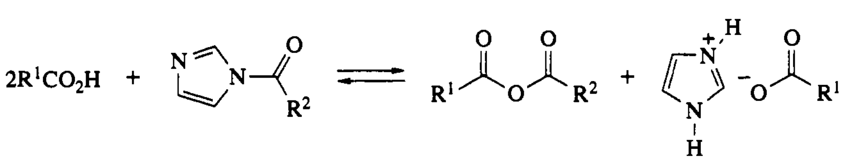
(33)

Carbodiimides, in particular dicyclohexylcarbodiimide, have been applied in many syntheses where dehydration had to be performed under mild conditions. It is therefore no surprise that this reagent was also introduced for the synthesis of acid anhydrides from carboxylic acids.[114,115] In order to avoid *N*-acylation the reactions are carried out at low temperature. First *O*-acylisoureas are formed, which then react further with free acid to the acid anhydride (equation 34). The reaction has been exploited in particular for the preparation of peptides.[116] *N*-alkoxycarbonyl-protected amino acids can be transformed in high yield to the corresponding anhydrides, which themselves are activated acid derivatives and may be converted to peptides. As in many other examples polymer-bound carbodiimides may prove superior sometimes, as the isolation of the products is facilitated. Easy preparation of acid anhydrides is possible in this way.[117]

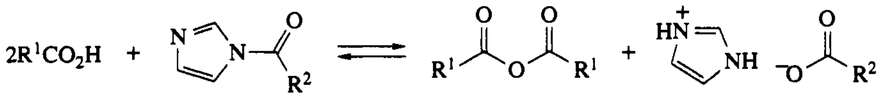


(34)

The use of imidazolides in organic synthesis has been propagated by Staab and coworkers.[118,119] Acid anhydrides can also be prepared with carbonyldiimidazolide. The reaction of a carboxylic acid with this reagent leads to acid anhydride if the transacylation equilibrium (equation 35) can be shifted to the side of the anhydride. This is possible either if the acid is used in twofold excess and forms an insoluble salt with the liberated imidazole or if trifluoro- or trichloro-acetylimidazolide is taken as the reagent. Symmetrical acid anhydrides can be obtained in a number of cases in good yield according to equation (36).[120]



(35)

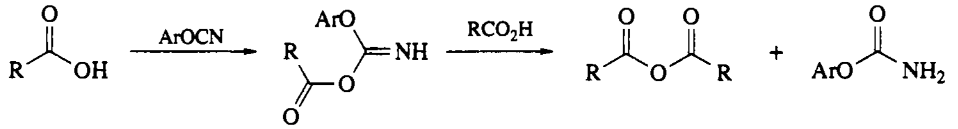


(36)

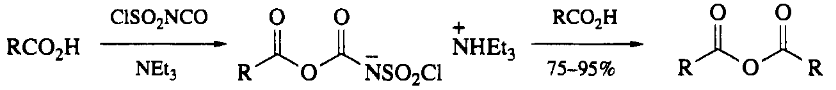
$R^2 = CCl_3, CF_3$

Another general approach to acid anhydrides from carboxylic acids was developed with esters of cyanuric acid as reagents (equation 37).[121] If the reactions are carried out in solvents like carbon tetrachloride or benzene, the resulting aryl esters of carbaminic acid are insoluble and can be removed by filtration.

Chlorosulfonyl isocyanate was introduced by Olah for the preparation of acid anhydrides. Under very mild conditions it is even possible to obtain formic acid anhydride.[122] This method has been applied successfully to other examples (equation 38).[123]



(37)



(38)

### 2.1.3.2 Acid Anhydrides from Carboxylic Acid Salts and Acid Halides

One of the classic procedures for the preparation of acid anhydrides is based on the reaction of metal salts of acids with acid halides. It offers the opportunity to obtain symmetrical and unsymmetrical acid anhydrides. A number of different metal salts have been applied over the years.

For the reaction of sodium salts with acid halides a procedure was developed which allows preparation of acid anhydrides in aqueous solution in the presence of a tertiary base (Table 8).

**Table 8** Acid Anhydrides from the Reaction of Sodium Carboxylates with Acyl Chlorides

| *$R^1COCl$* | *$R^2CO_2Na$* | *Yield (%)* |
|---|---|---|
| Ph | Ph | 97 |
| Ph | *o*-ClPh | 79 |
| *o*-ClPh | Ph | 96 |
| Ph | *p*-BrPh | 75 |
| Ph | *p*-$O_2$NPh | 64 |
| $Me(CH_2)_5$ | $Me(CH_2)_5$ | 94 |
| $Me(CH_2)_{14}$ | $Me(CH_2)_{14}$ | 75 |

Pyridine is used in catalytic amounts and acylpyridinium salts are assumed to be the reactive acylating agents. The method can be applied to the synthesis of both symmetrical and unsymmetrical acid anhydrides.[124] These can also be obtained in many cases directly from the acid halide and the sodium carboxylate without using a solvent or a catalyst. This approach has been described for a number of mixed acid anhydrides. Thus acetic palmitic anhydride (70%), butyric myristic anhydride (81%) and caproic lauric anhydride (85%) were prepared by heating the components for 2 h at 90 °C.[125] These anhydrides were successfully employed for the *N*-acylation of amino sugars.[126]

Peptides are also acetylated with the mixed anhydride of acetic acid and formic acid. The latter is made by the reaction of acetyl chloride with sodium formate in yields of 80–90%.[127] Mixed formic anhydrides with several carboxylic acids are obtainable with a copolymer of 4-vinylpyridine 1-oxide as catalyst. The reactions are carried out in acetonitrile with equimolar amounts of acid chloride and sodium formate. In most cases the mixed anhydride is the major product (Table 9).[128] The reactions are thought to proceed according to equation (39).

A solid phase copolymer of 4-vinylpyridine is a highly effective catalyst for the synthesis of acid anhydrides from mixtures containing equimolar quantities of carboxylic acids and acid chlorides.[129] The reaction can be simplified even more if a mixture of carboxylic acid and one-half equivalent of thionyl chloride in dichloromethane is treated with the solid state copolymer of 4-vinylpyridine. The conversion is accomplished equally well in batch or column mode.[130] Some examples are given in Table 10.

Several other metal salts have been proposed to react with acid halides to give acid anhydrides in good yield. Thus, thallium carboxylates in etheral suspension may be treated with acid halides to lead to acid anhydrides in high yield. The method has the advantage that thallium chloride can be separated by filtration and the product is isolated after evaporation of the solvent.[131] Another synthetic possibility exists in the desulfurization of thioesters with mercury(II) carboxylates.[132] Mercury(II) carboxylates can also be reacted with triethyl phosphite or tri-*n*-butylphosphine to provide acid anhydrides in yields of 60–80%.[133] Another possibility is offered by the reaction of 1 mol of *N*,*N*-dicyclohexylthiourea and 2 mol of silver or mercury(II) carboxylates.[134] Mixed carboxylatocarbamato anhydrides follow from the room temperature reaction of *N*,*N*-dialkylcarbamato metal derivatives with acid chlorides. Either Na, $Cu^{II}$, $Ti^{III}$ or $V^{III}$ are employed.[135]

### 2.1.3.3 Acid Anhydrides by Miscellaneous Methods

Mild dehydrating agents are available in yneamines[136] and 1-alkoxyalkynes.[137] They have been applied occasionally to the preparation of acid anhydrides.[136–139] The great advantage of these reagents is that the reaction takes place under neutral conditions and, therefore, acid anhydrides of acid sensitive compounds can be obtained. An extension of this approach was described recently. Trimethylsilylethoxyacetylene, which can be prepared from ethoxyacetylene, serves as a very mild dehydrating agent.[140] By means of this compound various types of acid sensitive carboxylic acid anhydrides can be made quantitatively or almost quantitatively (equation 40). Some examples are collected in Table 11.

Direct catalytic oxidative carbonylation to form acid anhydrides was achieved with arylmercury acetate.[141] Palladium(II) salts are taken as catalysts. Aromatic compounds such as benzene, toluene, anisole, furan, thiophene and naphthalene can be converted catalytically with palladium(II) acetate and an excess of 1,2-dibromoethane to acid anhydrides in yields of 30–60%.[142]

Of commercial interest is the preparation of acid anhydrides from hydrocarbons by direct oxidation. This methodology has been developed in particular for the synthesis of cyclic anhydrides, which are then introduced for the production of polymers.[143]

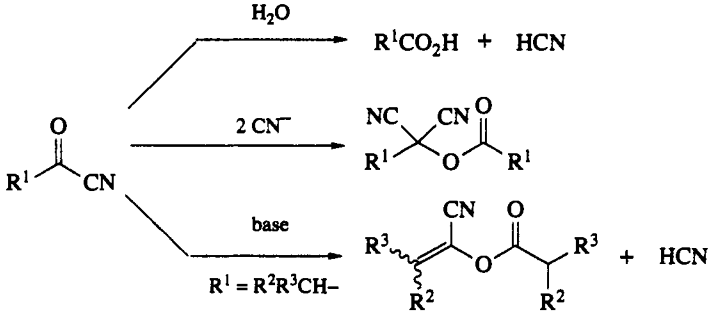
## 2.1.4 α-KETONITRILES

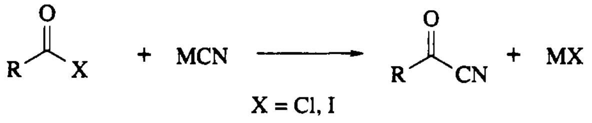
The characteristic feature of α-ketonitriles is the presence of two functional groups, which are capable of adding nucleophiles, next to each other. The electron-withdrawing character of the cyano group leads to enhanced electrophilicity of the carbonyl group, even though the carbonyl activity is less pronounced than in acid halides. Also, the cyano group displays increased reactivity towards nucleophiles as a consequence of the directly attached carbonyl group. These compounds are valuable intermediates for the synthesis of heterocycles. An earlier review[144] has found an actualization more recently.[145] Some information on their preparation can be obtained from Houben–Weyl.[146,147] The synthesis of acyl cyanides starts in general from cyanuric acid or its metal salts and reacts them with acid halides. Most α-ketonitriles are colorless liquids or solids. In the preparation of these compounds it has to be considered that they are mild acylating agents, that they dimerize in the presence of excess cyanide ion and that enolizable derivatives are converted in the presence of base to acylated enols (equation 41).



(41)

### 2.1.4.1 α-Ketonitriles from Acid Halides

Due to the sensitivity of acyl cyanides towards excess cyanide ions it is in general advisable not to use alkali metal cyanides as reagents unless special conditions are secured. Therefore, in most cases cyanides of heavy metals (low concentration of free cyanide) have been applied. These transformations require rather drastic conditions, which restricts the application mainly to the preparation of aromatic acyl cyanides. The latter can be obtained in good yield if copper(I) cyanide is heated with acid chlorides in aromatic solvents for several hours at temperatures of 160 °C.[148] More recent developments are based on the same strategy, but allow the application of milder conditions. In most cases acid chlorides are converted to acyl cyanides. Some reagents and the reaction conditions for their application according to equation (42) are collected in Table 12.



(42)

**Table 12** Preparation of Acyl Cyanides from Acyl Halides

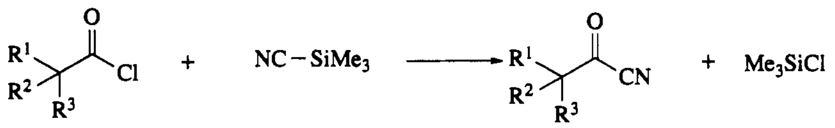
| $Bu^n{}_3SnCN$ | 75 °C, 5 min | Aryl | 80–95 | 156 |

Compared to the older procedures the use of acid iodides in acetonitrile or dichloromethane as solvent constituted a remarkable improvement.[149] Aromatic and aliphatic acyl cyanides are accessible by this route. For example acyl cyanides of cinnamic acid and phenylacetic acid could be obtained in 53% and 49% yields. Copper(I) cyanide in diethyl ether in the presence of lithium iodide gave α-cyano ketones in 50–70%.[150] The reaction can be carried out at room temperature in diethyl ether or slightly above or at 80 °C in acetonitrile. It is not possible to obtain the acyl cyanide from acryloyl chloride, chloroformate or oxalyl chloride by this approach.

Thallium(I) cyanide was introduced by Taylor and McKillop as a reagent.[151] Aromatic and heteroaromatic acyl cyanides are produced in good yield, whereas aliphatic acid halides lead under these conditions mainly to dimerization products. 18-Crown-6 is a good catalyst for the preparation of cyanoformate in methylene chloride with potassium cyanide and chloroformates.[153] Similarly, tetraethylammonium cyanide gives cyanoformates in high yield under very mild conditions.[154] Aroyl cyanides are generated easily by phase transfer catalysis with tetra-*n*-butylammonium bromide.[155] Tri-*n*-butyltin cyanide proved successful only with aromatic acid halides, leading to dimerization products with aliphatic compounds.[156]

A general method for the preparation of α-cyano ketones from acid halides was developed recently (equation 43).[157,158] With trimethylsilyl cyanide as reagent a great number of acyl cyanides can be prepared under mild conditions in high yield. In particular the synthetically useful aliphatic derivatives have become accessible by this reaction. Table 13 lists examples for aliphatic, α,β-unsaturated and benzylic acyl cyanides. The procedure is very simple in that trimethylsilyl cyanide and acid chloride are mixed and kept without solvent. The reaction is followed by IR spectroscopy. As soon as all of the trimethylsilyl cyanide is consumed, the product can be isolated, normally by distillation, or directly used for further reactions.

Sometimes a Lewis acid such as zinc iodide is added in catalytic amounts. Side reactions may sometimes occur if acyl cyanides carry hydrogen atoms in the α-position and are, therefore, enolizable. In those examples trimethylsilyl chloride, which is formed during the reaction, may react to give trimethylsilylated enol ethers (**8**). This methodology can be applied successfully to the synthesis of such com-



(43)

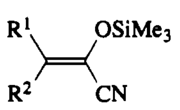
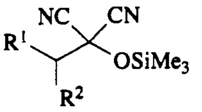
[a] Yields and purity determined by IR spectroscopy.

pounds.[145] Sometimes excess trimethylsilyl cyanide may add to the carbonyl group of the α-ketonitrile leading to compounds of type (**9**). The latter reaction is predominant for carbonyl chloride, oxalyl chloride and trifluoroacetyl chloride. Compounds of type (**8**) can be taken to generate α-halo substituted acyl cyanides through reaction with halogens.



(**8**)



(**9**)

### 2.1.4.2 α-Ketonitriles by Miscellaneous Methods

α-Cyano ketones have been prepared from derivatives of aldehydes and ketones (equation 44),[159] in particular aromatic derivatives. Oxidation of aromatic cyanohydrins (equation 45) is another possibility.[160] More recently catalytic cyanocarbonylation of aryl iodides has been advanced.[161]

# 2.2

# Synthesis of Esters, Activated Esters and Lactones

JOHANN MULZER
*Freie Universität Berlin, Germany*

2.2.1 FORMATION OF ESTERS AND ACTIVATED ESTERS 324
- *2.2.1.1 General Introduction* 324
- *2.2.1.2 Synthesis of Esters by Acyl Transfer to Alcohols (Carboxy Group Activation, CGA)* 324
  - *2.2.1.2.1 Esters from carboxylic acids and alcohols under acid catalysis: the $A_{Ac}2$ and $A_{Ac}1$ mechanism* 325
  - *2.2.1.2.2 Acyl transfer* via *anhydrides and acid chlorides* 327
  - *2.2.1.2.3 Acylation with mixed anhydrides and activated esters* 328
  - *2.2.1.2.4 Acylation with ketenes* 332
  - *2.2.1.2.5 Acylation with* N-*acylimidazoles* 333
- *2.2.1.3 Esters from Carboxylic Acids and Alcohols* via *Hydroxy Group Activation (HGA)* 333
  - *2.2.1.3.1 Mitsunobu reaction* 333
  - *2.2.1.3.2 Eschenmoser–Vorbrüggen reaction* 334
- *2.2.1.4 CGA and HGA Esterifications at Will: the DCC Method* 334
- *2.2.1.5 Alkylative Esterification* 335
- *2.2.1.6 Selective Monoacylation of Polyols* 337
- *2.2.1.7 Transesterifications* 339
- *2.2.1.8 Enzymatic Acylations and Deacylations* 340

2.2.2 SYNTHESIS OF LACTONES 342
- *2.2.2.1 Synthesis of α-Lactones* 342
- *2.2.2.2 Synthesis of β-Lactones* 342
  - *2.2.2.2.1 β-Lactones* via *cycloalkylation* 345
  - *2.2.2.2.2 β-Lactones* via *cycloacylation* 346
  - *2.2.2.2.3 β-Lactones from β-hydroxy carboxylic acids with HGA and CGA reagents* 347

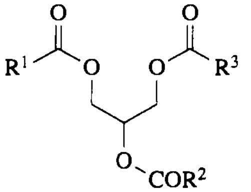
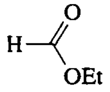
## 2.2.1 FORMATION OF ESTERS AND ACTIVATED ESTERS

### 2.2.1.1 General Introduction

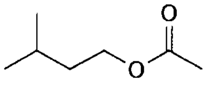
The formation and further transformation of esters belongs to the fundamentals of organic chemistry. Moreover, some esters have enormous importance; for example triglycerides (**1**), in the form of fats and oils, are produced in million ton quantities for a number of applications. Other esters, *e.g.* (**2**) and (**3**), are olifactory components; waxes, *e.g.* (**4**), are used commercially to protect metallic surfaces against corrosion. Aspartame (**5**) is an important artificial sweetener, and pyrethrin (**6**) is the prototype of the pyrethroids, an unusually potent class of insecticides.[1] Apart from these more applied considerations, esters are important synthetic intermediates in a number of multistep sequences. Striking examples are chain elongations *via* Horner alkenation or α-alkylations of ester enolates, in particular the ones stereocontrolled by chiral auxiliaries.[2]



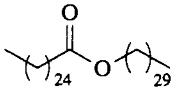
(**1**)



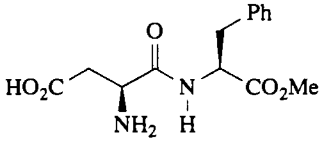
(**2**)



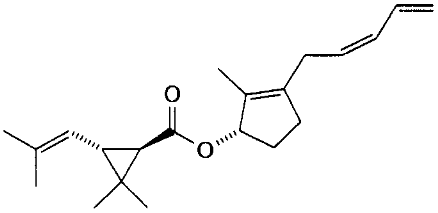
(**3**)



(**4**)



(**5**)



(**6**)

The simplest route to esters is the esterification of carboxylic acids. This subject has been covered in a number of more or less comprehensive reviews.[3] Therefore, the present report can be restricted to the most significant and recent developments.

### 2.2.1.2 Synthesis of Esters by Acyl Transfer to Alcohols (Carboxy Group Activation, CGA)

This method for the synthesis of esters is the most common method (equation 1). The carboxylic acid or an activated derivative thereof (**7**) is treated with the alcohol (**8**), generally in presence of a base, so that eventually the activating group X is replaced by the $OR^2$ moiety to form the ester (**9**). In effect this reaction is an $S_N$ process at a trigonal carbon center and may proceed *via* an addition–elimination ('$S_N2$') or an elimination–addition ('$S_N1$') sequence. In either case, the configuration with respect to the $R^2$—O bond is retained and no $^{18}O$ exchange of this oxygen is observed.[4] X must be a good leaving group on one hand as in the aliphatic $S_N$ reactions and, additionally, its electron donation to the carbonyl function must be minimalized.

### 2.2.1.2.1 *Esters from carboxylic acids and alcohols under acid catalysis: the* $A_{AC}2$ *and* $A_{AC}1$ *mechanism*

This method is extremely simple and is to be preferred if one of the components is cheap and both the acid and the alcohol do not contain acid sensitive functional groups. As catalysts conc. HCl (Fischer–Spei esterification), anhydrous sulfuric acid or *p*-toluenesulfonic acid or acidic ion exchange resins may be employed. The alcohol generally serves as the solvent, if permitted by its costs, otherwise toluene or xylenes may also be used. A very efficient catalyst is graphite bisulfate in cyclohexane.[5] The reaction generally leads to an equilibrium mixture consisting of about 80% of the ester and 20% of the components. Complete ester formation can be accomplished either by using the alcohol in large excess, *e.g.* as the solvent, or by removing the water from the mixture, for example by means of a Dean–Stark apparatus or a desiccating agent, preferrably 3Å molecular sieve. Volatile esters may be removed from the mixture by distillation. Instead of the proton acids mentioned above, Lewis acids such as boron trifluoride or polymer-supported aluminum chloride and chlorosilanes, may also be used. The advantage of these procedures lies in the high yields and the purity of the esters. Table 1 shows some illustrative examples.

**Table 1** Acid-catalyzed Esterifications

$$R^1CO_2H + R^2OH \longrightarrow R^1CO_2R^2 + H_2O$$

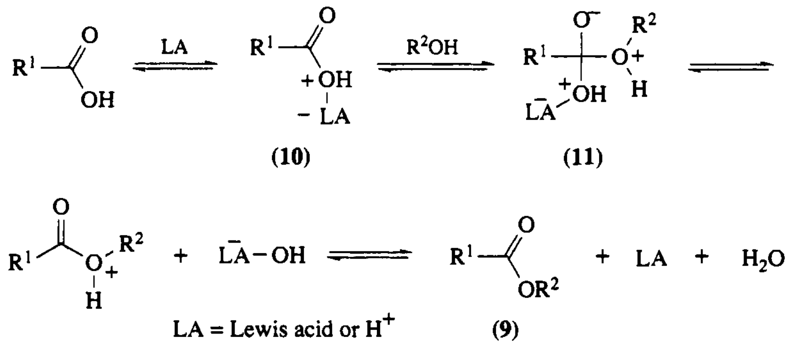
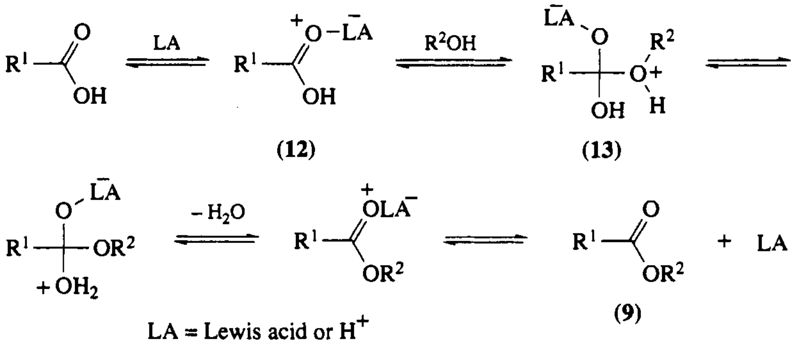
|  | Me | $Me_3SiCl$ | — | 84 | 16 |

The widely accepted mechanism of the acid-catalyzed esterification is designated as the $A_{AC}2$ process (A = acid catalysis, AC = acyl transfer, 2 = bimolecular). As shown in Schemes 1a and 1b the rate-determining step is the reversible attack of the alcohol at the carbonyl function of the activated species (**10**) and (**12**). Two modes of proton (or Lewis acid) activation may be distinguished: either protonation of the OH function (Scheme 1a), leading to (**10**) and (**11**), or protonation of the carbonyl oxygen (Scheme 1b), leading to (**12**) and (**13**). Although the first mechanism is generally formulated in the literature, the second mechanism appears far more plausible regarding the site of the initial protonation,[17] as well as the lesser degree of charge separation in the crucial intermediates (**11**) *versus* (**13**).



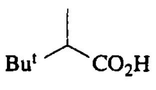
**Scheme 1a**



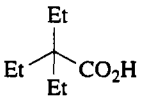
**Scheme 1b**

*(i) Scope and limitation of the $A_{AC}2$ esterifications*

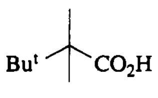
The greatest advantage of the method lies in its simplicity; however, the rather severe conditions (extended heating in presence of a mineral acid) makes it questionable for sensitive substrates. Additionally, α- and β-branching in the carboxylic acid strongly retards the reaction, so that for example, acids (**14**)–(**16**) are too hindered to react. On the other hand, α- and β-branching in the alcohol induces dehydration.



(**14**)



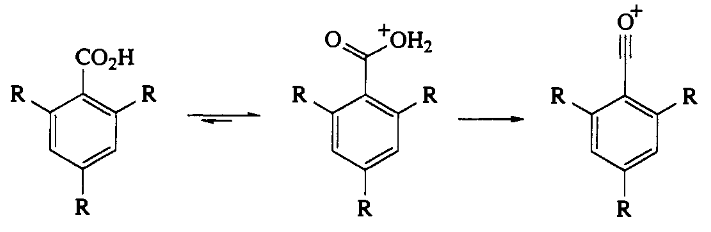
(**15**)



(**16**)

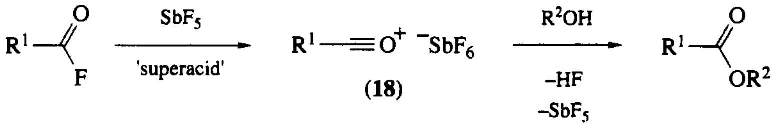
*(ii) The $A_{AC}1$ mechanism*

This mechanism (A = acid catalyzed, AC = acyl transfer, 1 = unimolecular) is observed in the esterification of 2,4,6-trisubstituted benzoic acids with R groups of moderate +M effect (*e.g.* methyl).[17] The $A_{AC}2$ mechanism is blocked by the steric interference of the *ortho* substituents. Therefore, the acylium cation (**17**) is generated with anhydrous sulfuric acid and then treated with the alcohol (equation 2).[18] R groups with strong +M effects, like methoxy, are not tolerable, as the aromatic nucleus undergoes sulfonation under the conditions. A variation of the $A_{AC}1$ mechanism for aliphatic acids is achieved by using the fluorides and antimony pentafluoride to generate the acylium ion (**18**),[19] which reacts even with strongly hindered alcohols to form the esters (equation 3).



**(17)**

(2)



(3)

### *2.2.1.2.2 Acyl transfer via anhydrides and acid chlorides*

In contrast to the $A_{AC}$ esterifications this method makes use of preformed CGA species (**19**) and (**20**) to which the alcohol is added. The formation of acid chlorides[20] requires strong Lewis acids like thionyl or oxalyl chloride, which may react with acid sensitive functions in the molecule and also cause epimerization of chiral α-centers in the substrate molecule. On the other hand, using anhydrides (**20**) for esterification means to lose 1 mol equiv. of the acid. Thus, both (**19**) and (**20**) should preferentially be used for inexpensive carboxylic acids with a low degree of functionalization. Typical and frequently encountered examples in multistep syntheses are benzoylation and acetylation of primary and secondary alcohols, whereas tertiary alcohols are generally too hindered to react, unless a strong base catalyst (*e.g.* calcium hydride)[21] is added. The acetylations are normally performed in pyridine at 0–25 °C. Acid catalysis is less common. Acid chlorides can be used in pyridine or in dichloromethane with triethylamine as the base. In any case, the anhydride should be preferred, as the reaction mixture remains almost neutral throughout the reaction and the yields are higher, particularly if the acylation is catalyzed with *N*,*N*-dimethylaminopyridine (DMAP; **21**) or, even better, 4-pyrrolidinopyridine (PPY; **22**).[22] Regular conditions are 0.05–0.2 mol equiv. of the catalyst in aprotic solvents (hexane, dichloromethane, THF, pyridine) at room temperature. Rate enhancements compared to the uncatalyzed reactions are several powers of ten, so that even hindered hydroxy functions (*e.g.* in **23** or **24**) are smoothly acylated.

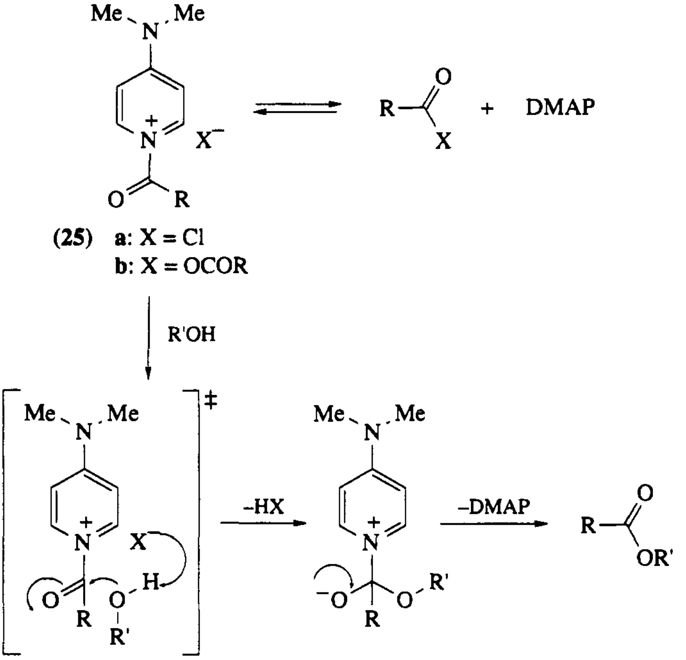
### *(i) Mechanistic aspects*

Mechanistically, the alcoholysis of acid chlorides may proceed *via* a one step $S_N2$-like mechanism or more frequently, *via* the usual tetrahedral intermediate.[23] The reaction is accelerated by electron-withdrawing substituents in the chloride and hardly affected by steric hindrance. On the other hand, benzoyl chlorides with electron-releasing substituents in the aromatic nucleus undoubtedly react *via* an $S_N1$-like mechanism, especially in protic solvents.[24] Anhydrides prefer the normal addition–elimination pathway, the rate-determining step being the formation of the tetrahedral intermediate. The drastic effect of the catalysts (**21**) and (**22**) may be attributed to the initial formation of the acyl pyridinium salt (**25**), in which $X^-$ serves as the base for the deprotonation of the alcohol during its nucleophilic attack on the carbonyl group (equation 4). This explains why acid chlorides show much smaller rate enhancements with (**21**) and (**22**) than anhydrides, although the equilibrium concentration of (**25a**) is much higher than that of (**25b**). However, chloride is a much weaker base than the carboxylate and cannot remove the proton from the alcohol with similar efficiency. Additionally, $X^-$ must be close to the reaction site, which means that (**25**) is more efficient an acylating agent as a contact than as a solvent-separated ion pair. In fact, the rates are much higher in unpolar than in polar solvents.



(**25**) **a**: X = Cl
**b**: X = OCOR

(4)

### *2.2.1.2.3 Acylation with mixed anhydrides and activated esters*

This acylation process is of the utmost importance. In the first step, the carboxylic acid is treated with an activating agent X—Y to form the CGA species (**26**), which acylates the alcohol in the second step. X is a substituent with a strongly electron-withdrawing –I- or –M-effect and Y is a good leaving group. If X contains an acyl function, as in cases a–d, (**26**) is a mixed anhydride; otherwise, for instance in cases e–i, (**26**) is classified as an activated ester. In both types, the activating effect of X is two-fold ('double activation')[25] in facilitating the nucleophilic attack of the alcohol.

As shown in Scheme 2, the electron-withdrawing character of X enhances the electropositive nature of the carbonyl carbon in (**26**). The second, and equally important, effect is the ability of X to accept the proton from the alcohol. In this manner the effective nucleophilicity of the alcohol is drastically increased in the immediate proximity to the reactive center. Thus, (**26**) behaves very similarly to (**25**), with the only difference that (**26**) is neutral and (**25**) is an ion pair. As an additional benefit of the proton transfer, the leaving group quality of the OX fragment is also greatly improved.

Mixed anhydrides from carboxylic acids (**26a**) have to be so devised that the desired acyl group is transferred. This can be achieved in two ways. The first one is to block the undesired carbonyl position by steric (*e.g.* **26aa**; equation 5) or electronic (*e.g.* **26ab**; equation 6) deactivation. The second one, as illustrated by (**26ac**; equation 7) is to allow the reversible attack of both carbonyl groups; the desired acyl transfer is accomplished by the better leaving group quality of the trifluoroacetate. Specifically, the

mixed anhydrides (**26aa**) and (**26ab**) are prepared from the carboxylic acid and 2,4,6-trichlorobenzoyl chloride and methyl(ethyl)chloroformate in an aprotic solvent (THF, dichloromethane, *etc.*) in the presence of triethylamine. In the case of (**26aa**), the solvent is then replaced by benzene and the alcohol and a catalytic amount of DMAP (**21**) are added (equation 5).[26] On the other hand, (**26ab**) is heated to eliminate carbon dioxide under formation of the ester. This reaction, however, requires an $R^1$ group with electron-withdrawing substituents (equation 6).[27] (**26ac**) is formed from the carboxylic acid and trifluoroacetic anhydride in benzene at about 50 °C, then the alcohol is added without a catalyst (equation 7).[28]

Similarly, the acyl tosylates (**26b**) are prepared from the acid and tosyl chloride in pyridine at 0 °C; then the alcohol is added (equation 8). In view of the basic medium this method is particularly suited for acid sensitive alcohols (tertiary, propargylic, allylic or homoallylic).[29] The acyl phosphate (**26c**) is made

from the carboxylic acid and the chlorophosphate[27] in the presence of triethylamine. The alcohol only reacts with the mixed anhydride (**26c**) and not with the chlorophosphate, which means that it can be added together with the carboxylic acid (equation 9).[30] In a similar way, phosphoric ester dichlorides may be reacted with carboxylic acids to form mixed anhydrides (**26d**) in DMF and after addition of the alcohol component, esters are formed in high yields.[31]

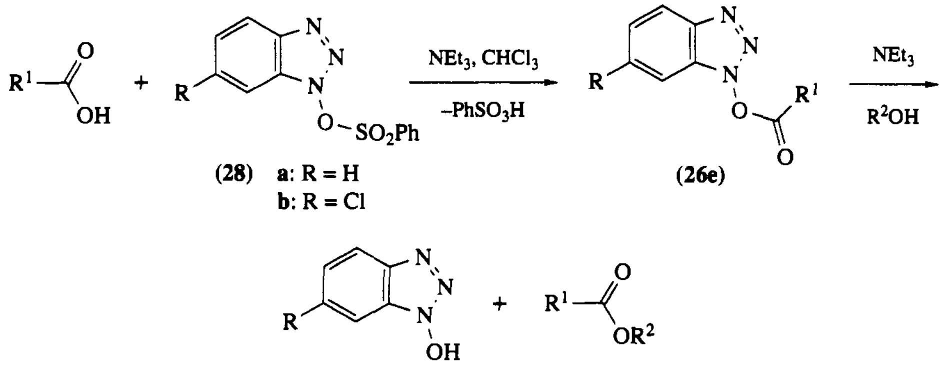
### *(i) Activated esters*

Like the mixed anhydrides, activated esters may also be represented by the general formula (**26**). The only difference between mixed anhydrides and activated esters lies in the fact that HOX corresponds to a carboxylic or inorganic proton acid in the case of the mixed anhydrides and to an (acidified) alcohol in the case of the activated esters. In all other respects the overall procedure is very similar to that used for mixed anhydrides. For example (equation 10), the 1-acyloxy-1,2,3-triazole derivatives (**26e**) are formed from the carboxylic acid and the benzenesulfonates (**28**). Triethylamine is used to neutralize the sulfonic acid and to catalyze reaction of the alcohol with (**26e**).[32] The advantage of this method lies in the high selectivity; primary alcohols are acylated with high preference over secondary ones (see Section 2.2.1.6).

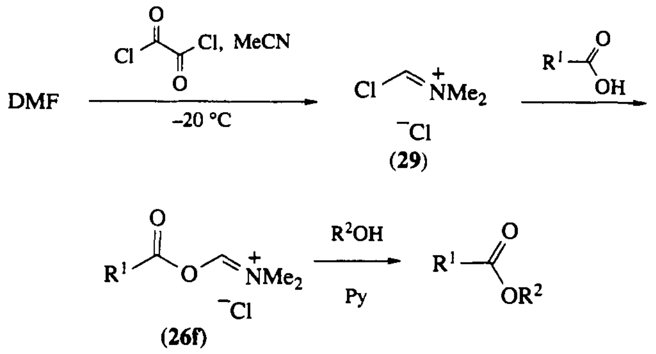


(**28**) **a**: R = H
**b**: R = Cl

(**26e**)

(10)

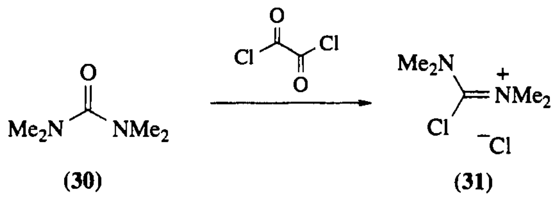
Chloroformamidinium chlorides (**29**) are generated from DMF and oxalyl chloride in acetonitrile. After addition of the carboxylic acid the activated ester (**26f**) is formed and treated with a solution of the alcohol in pyridine.[33] Phenyl, alkyl and even *t*-butyl esters may be prepared in yields of greater than 80% (equation 11). Reagent (**31**), accessible from (**30**) and oxalyl chloride (equation 12) behaves quite similarly to (**29**).[34] The use of silyl esters (**26g**), which are formed *in situ* in the presence of the alcohol and react then to the esters, has already been mentioned in Section 2.2.1.2.1. An application is described in Table 1.



(**29**)

(**26f**)

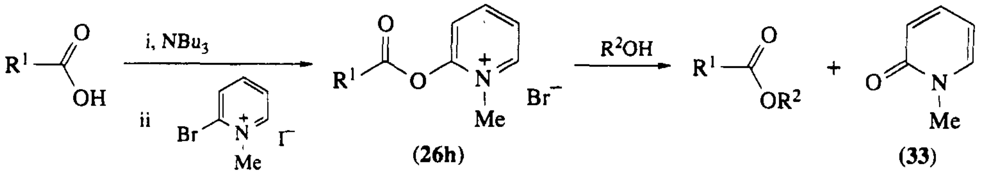
(11)



(**30**) (**31**)

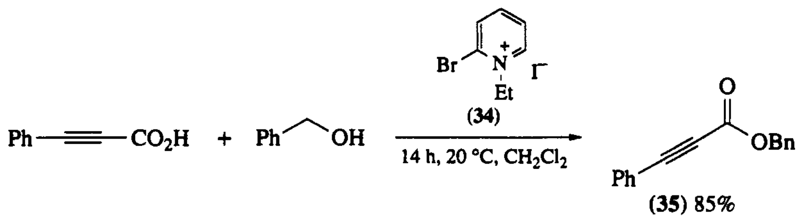
(12)

2-Acyloxypyridinium salts (**26h**) acylate various primary, secondary and tertiary alcohols under very mild conditions. All components (carboxylic acid, **32**, tributylamine and the alcohol) are stirred in dichloromethane at room temperature for several hours[35] to form the desired ester and pyridine (**33**; equation 13). The ester is isolated by chromatography. The synthesis of benzyl phenylpropiolate (**35**) may serve as an example (equation 14).



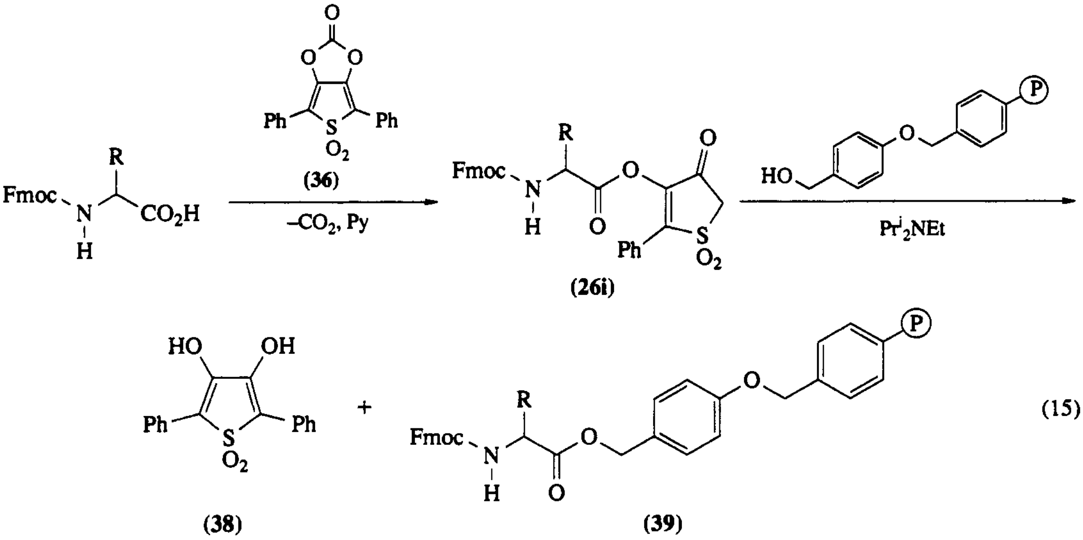
(**32**) (**26h**) (**33**)

(13)



(14)

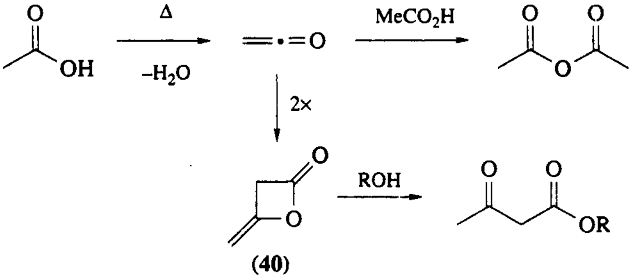
The novel carbonate (**36**) has been developed by Steglich and coworkers[36] to solve a fundamental problem in solid-phase peptide synthesis, *i.e.* the attachment of the terminal *N*-protected amino acid to the Merrifield resin without racemization. To this end, the Fmoc-protected acid is treated with (**36**) to form the activated ester (**26i**), which may be isolated, and is then added together with Hünig's base to the *p*-benzyloxybenzyl alcohol substituted resin. Under elimination of (**38**) the desired immobilized ester (**39**) is formed, from which the Fmoc group is removed with piperidine. The next amino acid can be condensed to the amino group, again using (**36**) as the coupling agent (equation 15).[36]



(15)

## 2.2.1.2.4 *Acylation with ketenes*

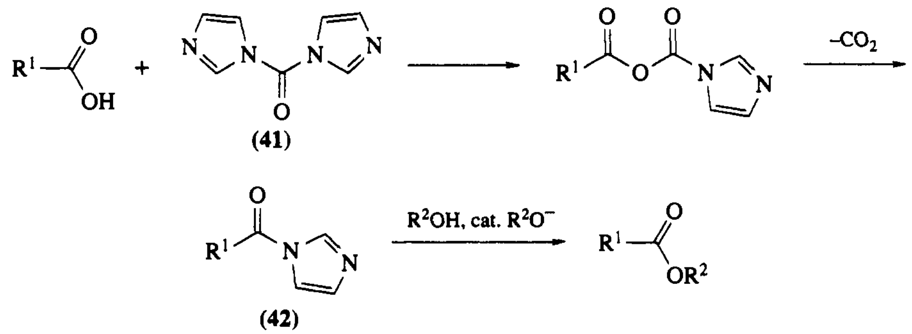
Ketenes are highly reactive acylating agents. However, they have found only limited application, as they are not as readily available as the other acylating agents described so far. The only exception is ketene itself, which is produced on a large scale industrially and is used for the acylation of acetic acid to acetic anhydride (1986, 1.6 millions of tons[37]). A minor amount (1986, 63 000 tons[37]) of ketene is dimerized to diketene (**40**), which is used to acylate alcohols to various esters of acetoacetic acid (equation 16). The corresponding amides are prepared analogously.



(16)

#### *2.2.1.2.5 Acylation with* N*-acylimidazoles*

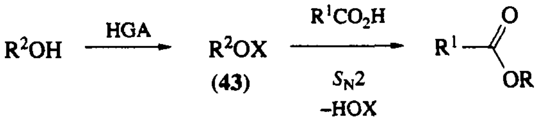
This method was introduced by Staab[38] and is suitable for the acylation of primary, secondary and tertiary alcohols. First the carboxylic acid is converted into the imidazolide (**42**) with carbonyldiimidazole (**41**), and then the alcohol is added together with a catalytic amount of strong base (alkoxide). The ester is formed at room temperature within a few hours (equation 17). If functional groups in the acid or alcohol prevent the use of base, the imidazolide and the alcohol have to be heated to 70 °C for 1–2 h.



(17)

### 2.2.1.3 Esters from Carboxylic Acids and Alcohols *via* Hydroxy Group Activation (HGA)

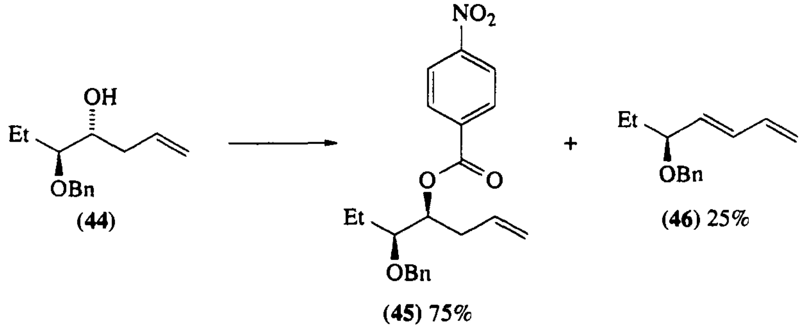
This type is a one-pot reaction with all components present from the beginning. The alcohol is first converted into an $S_N$-activated (HGA) species (**43**), which undergoes an OX displacement with the carboxylic acid to form the ester (equation 18). Two methods are known to fit into this general scheme: the Mitsunobu reaction[39] and the Vorbrüggen–Eschenmoser reaction.[40]



(18)

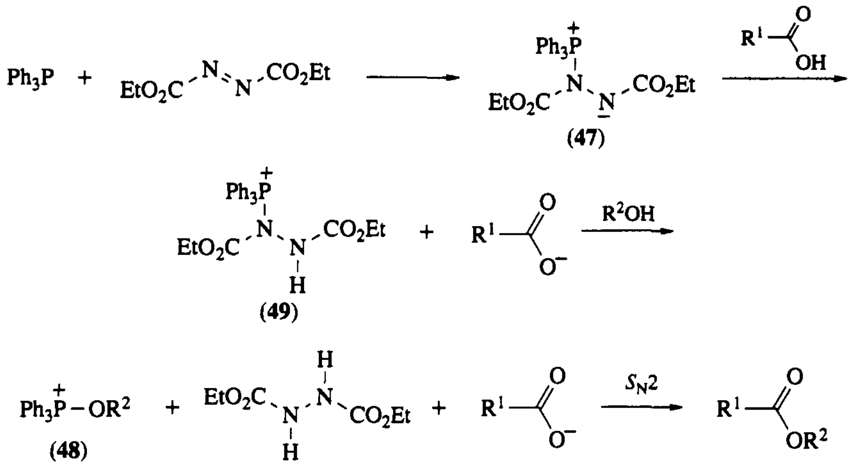
#### *2.2.1.3.1 Mitsunobu reaction*

This method is unusually mild, using neutral conditions and low temperatures (20 °C and less). It tolerates a number of functional groups in the components (*e.g.* acetals, esters, alkenes, *etc.*). The alcohol, the carboxylic acid and triphenylphosphine are treated dropwise in an inert solvent (dichloromethane, THF, ether) with diethyl azodicarboxylate (DEAD). The ester is formed rapidly. However, tedious chromatography is frequently required to remove the by-products, triphenylphosphane oxide and hydrazo ester. The main value of the reaction lies in the clean inversion of configuration at a secondary carbinol center and in its selectivity towards primary hydroxy groups (*vide infra*). Inversions are usually performed with benzoic or *p*-nitrobenzoic acid. The benzoates are purified and saponified with aqueous base to furnish the inverted alcohols in overall yields of *ca.* 50%. Elimination is the main side reaction. Thus, from (**44**) 75% of the desired $S_N$2 product (**45**) is formed, along with 25% of the elimination product (**46**) (equation 19).[41] The mechanism of the reaction has been clarified to the point that betaine (**47**) is the pri-



(19)

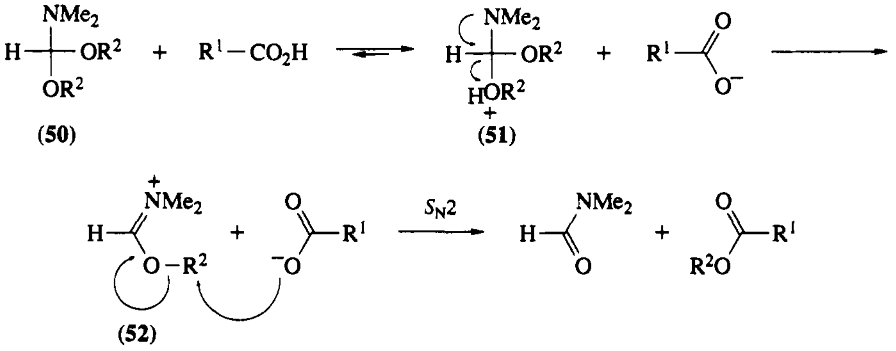
mary intermediate from which the triphenylphosphonium moiety is transferred to the alcohol from (**49**) to form the HGA species (**48**). The rate-determining step is the final $S_N2$ reaction with the carboxylate (equation 20).[42]



(20)

### 2.2.1.3.2 *Eschenmoser–Vorbrüggen reaction*

In this reaction the carboxylic acid is heated together with formamidacetals (**50**) in an inert solvent (benzene, *etc.*). The products are the ester, DMF and alcohol $R^2OH$. Only $S_N2$ active $R^2$ groups like methyl, ethyl, benzyl *etc.* can be transferred. Mechanistic studies have shown that the HGA species (**52**) is generated from (**50**) *via* elimination of $R^2OH$ under proton donation from the carboxylic acid. The carboxylate in turn undergoes an $S_N2$ displacement with (**52**) to form the ester and DMF (equation 21).

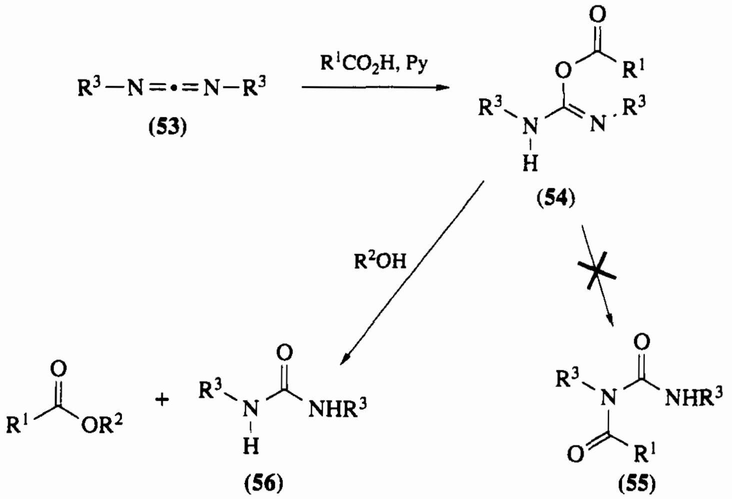


(21)

## 2.2.1.4 CGA and HGA Esterifications at Will: the DCC Method

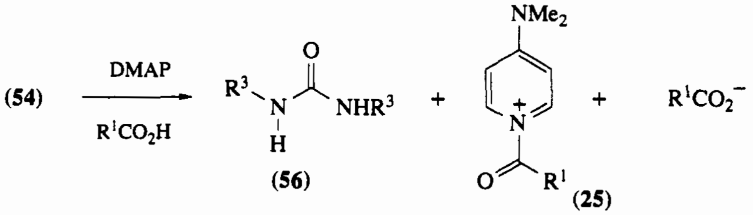
A reagent which allows both CGA and HGA esterifications is DCC (dicyclohexylcarbodiimide; **53**; $R^3$ = cyclohexyl). CGA esterifications are accomplished by treating a mixture of the carboxylic acid and the alcohol with DCC in hexane or pyridine with a catalytic amount of *p*-TsOH. The *O*-acylisourea (**54**) is postulated as intermediate, which reacts with the alcohol under elimination of the urea (**56**) and formation of the desired ester. The urea is removed by filtration (equation 22).[43] This method is highly recommendable if both the carboxylic acid and the alcohol are valuable and bear sensitive functional groups. Numerous applications in natural product synthesis have been reported.[44]

DMAP catalyzes the reaction most efficiently.[45] From (**54**) and excess carboxylic acid (**56**) the already described ion pair (**25**) is formed, which then acts as the acylating species proper. However, the carboxylate is not wasted in this case, as it reacts immediately with (**53**) and is thus recycled.[46] Thus, the DCC method can also be used for acylations with symmetrical anhydrides; now both acyl moieties are used in the esterification (equation 23).[46] The HGA variant is less common. To this end, the alcohol is first

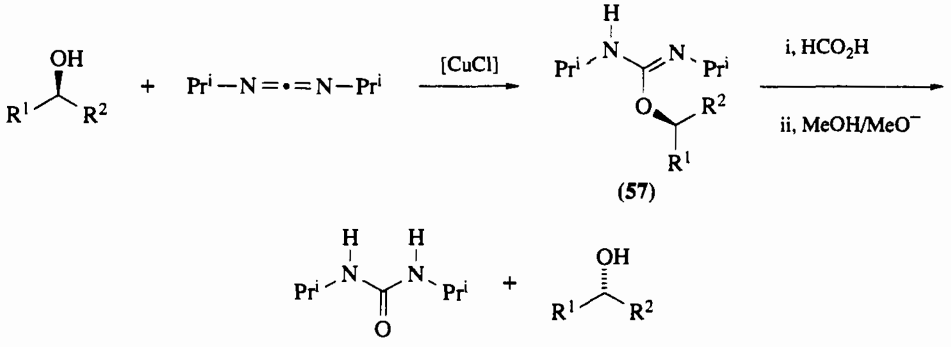


(22)

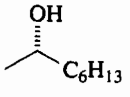
added to DCC under copper(I) catalysis to form the *O*-alkylisourea derivative (**57**), which is isolated and treated with the acid to form the ester *via* $S_N2$ displacement.[47] In effect, this reaction constitutes an alternative to the Mitsunobu reaction. The carboxylic acid used for the inversion of secondary carbinols is formic acid; the formates are saponified with methoxide (equation 24). The inversion of carbinols (**58**)–(**60**) proceeds with high overall yields.[48]



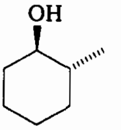
(23)



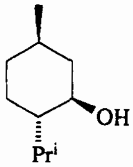
(24)



(**58**)



(**59**)

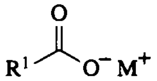


(**60**)

### 2.2.1.5 Alkylative Esterification

This type of esterification largely resembles the HGA reactions described in Section 2.2.1.3, with the only difference that the alkylating species is now an alkyl halide or tosylate or some quasi-carbenium ion instead of an activated alcohol (**43**). The most straightforward way of achieving alkylative esterification is by the treatment of carboxylate salts with an alkylating agent $R^2X$ (Table 2).

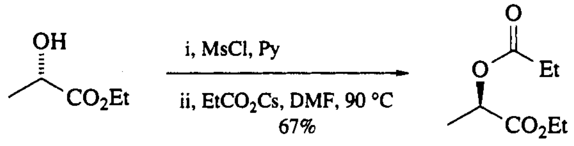
**Table 2** Alkylative Esterification



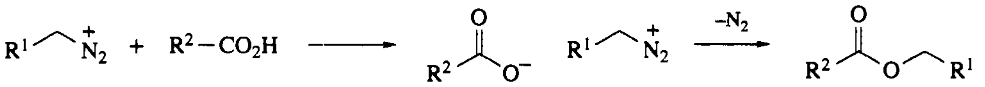
+ $R^2X$ X = OTs, OMs, Cl, Br

| *Compound* | *Ester* | *M* | *X* | *Yield (%)* | *Ref.* |
|---|---|---|---|---|---|
| **(61a)** |  | Na | Cl | 82 | 49 |
| **(61b)** |  | Na | OMs | 40 | 50 |
| **(61c)** |  | Na | Cl | 80 | 51 |
| **(61d)** |  | Ag | Br | 65 | 52 |
| **(61e)** |  | K | Br | Quantitative | 53 |
| **(61f)** |  | Na | Br | Quantitative | 54 |
| **(61g)** |  | Ag | I | 68 | 55 |
| (61h) |  |  | | 68 | 56 |

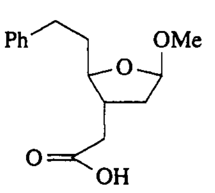
It will be noted from examples (**61a**)–(**61g**) that a wide variety of carboxylates can be used, suitable cations being Na, K or Ag. In particular $Ag^+$ in combination with an alkyl bromide or iodide permits the $S_N$ reaction even at branched $sp^3$-centers (**61d, 61f** and **61g**). Example (**61h**) illustrates the use of quaternary ammonium carboxylates in which on heating the alkyl substituent with the highest $S_N2$ activity (*e.g.* benzyl > ethyl or methyl) is transferred from N to O. The advantage of the alkylative esterification lies in the neutral conditions under which acid sensitive functional groups can survive (*e.g.* **61b** and **61c**). Like the Mitsunobu reaction and the CuCl-catalyzed DCC activation the alkylative esterification may be used for the inversion of configuration at secondary carbinol centers. For instance, lactic ester (**62**) is mesylated and then heated with cesium propionate in DMF[57] to give (**63**; equation 25). Diazoalkanes (**64**) react with carboxylic acids under proton transfer to give the diazonium carboxylate (**65**),[58] which collapses into the ester and nitrogen (equation 26). This method is the best for methylating sensitive carboxylic acids like (**66**).[59] The extension to diazoalkanes other than diazomethane, however, has been prohibited by their poor availability and the potential danger in handling these compounds. An established procedure for preparing *t*-butyl esters is the treatment of carboxylic acids with isobutene and strong acid in aprotic solvents (equation 27).[60]



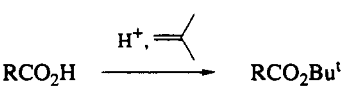
(**62**) (**63**) (25)



(**64**) (**65**) (26)



(**66**)



(27)

### 2.2.1.6 Selective Monoacylation of Polyols

One of the fundamental operations in multistep syntheses is the selective acylation of polyols, mainly for protection purposes, as selectivity in favor of one out of several hydroxy groups in general is far easier to get by acylation than by alkylation. The differentiation between tertiary and secondary or primary OH groups presents no problems, as tertiary groups are acylated only under forced conditions. Standard conditions (*e.g.* acetic anhydride or benzoyl chloride in pyridine) leave tertiary hydroxy groups untouched. Thus, only the secondary OH function in (**67**) is acetylated.[61] Even strongly hindered primary OH functions, *e.g* the one marked in (**68**), are unreactive.[62] A crucial problem, however, is the differentiation of primary and secondary positions, especially in 1,2-diols like (**70**), (**71**), (**75**) or (**76**). A variety of methods have been developed to solve this problem by selective benzoylation of the primary OH group with reagents like benzoyl cyanide, benzoylimidazole and benzoyltetrazole.[63] Recently, 1-benzoyl oxybenzotriazole (**69**) has been reported to furnish product ratios of primary to secondary benzoates of >90:10[64] in a number of cases, *e.g.* (**70**)–(**72**). The reagent even differentiates between secondary OH groups. So the marked positions in (**73**) and (**74**) are benzoylated with >90% selectivity. In favorable cases, primary OH functions in 1,2-diols can be selectively benzoylated simply by using benzoyl chloride in pyridine at –20 °C. (**75**) and (**76**) form the primary monobenzoates under these conditions with no concomitant acylation of the secondary position, but with formation of 5–10% of the dibenzoate.[65] Monobenzoylation of primary OH groups can also be achieved by the Mitsunobu reaction (Table 3).[39]

However, this method fails for 1,2-diols like (**79**) or (**81**), from which the epoxides (**80**) and (**82**) are generated (equations 28 and 29). This involves an $S_N2$-type cyclization with retention at the secondary

center.[66] The comparison between the *cis*- and *trans*-cyclohexane diols (**81**) and (**83**) is quite informative. Only the *trans* isomer gives the epoxide (equation 29), whereas the *cis* compound is monobenzoylated (equation 30). In suitable cases selective acylations with $Ac_2O$ may be achieved by utilizing conformational effects. For instance, in the forskolin precursor (**86**) only the marked OH group is acetylated under standard conditions. Due to the rigid conformation of the molecule this is the only secondary equatorial hydroxy function, whereas the other ones are either tertiary or axial.[67] Sometimes the need arises to get selective acylation of a secondary position in the presence of a primary one. This can be achieved by first peracetylating the compound and removing the more unhindered primary acetate with mild base. In this way, (**85b**) has been prepared from (**85a**) with perfect regiocontrol.[68] Further selective acylations are described in Section 2.2.1.8.

### 2.2.1.7 Transesterifications

Transesterifications can, in principle, be performed by reaction of esters with alcohols, carboxylic acids and other esters. All three types are reversible, so that the equilibrium has to be shifted to the desired side either by applying an excess of the reagent or by removing a volatile product *via* distillation. In all cases acid or base catalysis is required. In laboratory practice the most common transesterification method is the reaction of valuable esters with an excess of a cheap alcohol under the catalysis of a mild base. Examples are given in Table 4. Recently, $Ti(OPr^i)_4$ has been recommended as an exceptionally mild and efficient transesterification catalyst.[72] Thus, the dimethyl ester (**87**) is cleanly converted into (**88**) without affecting the acetonide ring (equation 31). The alcohol need not necessarily be identical with the OR group in the titanate, as this exchange is slow compared to the transesterification itself. Transesterifications of β-keto esters are most efficiently catalyzed with DMAP, as illustrated by equation 32.[73]

#### 2.2.1.8 Enzymatic Acylations and Deacylations

Enzymatic transacylations have received enormous attention in recent years.[74] The enzymes generally employed are lipases from microorganisms like *Candida cylindracea*, *Rhizopus arrhizus* or *Chromobacterium viscosum*, or from mammalian liver, like porcine pancreatic lipase (PPL). Ester hydrolysis is normally performed in water, sometimes with organic solvents (acetone or acetonitrile) as additives, whereas the acylations are run as transesterifications of the alcohol with esters with the enzyme in organic solvents (ether, benzene, *etc.*). The enzyme may be used as a crude extract or in purified form, sometimes entrapped in sepharose or in chromosorb as a solid support. The great advantage of the enzymatic process lies in its high chemo- and stereo-selectivity. For example selective monoacetylations of the primary OH function in methyl furanosides of D-ribose, D-arabinose, D-xylose and 2-deoxy-D-ribose with crude PPL in THF, using 2,2,2-trifluoroethyl acetate as the acyl donor, have been reported.[75] Optical resolution of racemic mixtures of alcohols can be efficiently achieved by enzymatic acylation or transesterification. In the ideal case, only one enantiomer is reactive, the other remains unchanged. In this way a variety of γ-branched alcohols (**89**) have been resolved with high *ee* values in both the ester and the remaining alcohol (Table 5 and equation 33).[76] α-Branched alcohols have been resolved with similar efficiency (Table 6 and equation 34).[76] The enzymes used were HLCE and yeast lipase on sepharose or chromosorb in water and the acyl-donating ester as solvent.

On the other hand, resolution of racemic α-halo carboxylic acids (**93**) with butanol can be effected with lipase (Table 7 and equation 35).[77] Applications of enzyme-catalyzed acyl transfer reactions, among many others, are the synthesis of the pheromone (*S*)-sulcatol (**95**; equation 36)[78] and of (*R*)-glycidylbu-

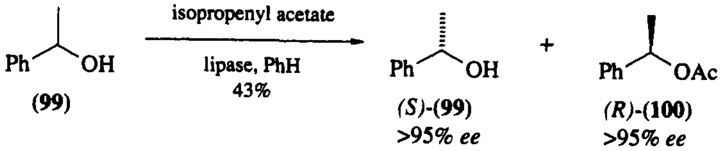
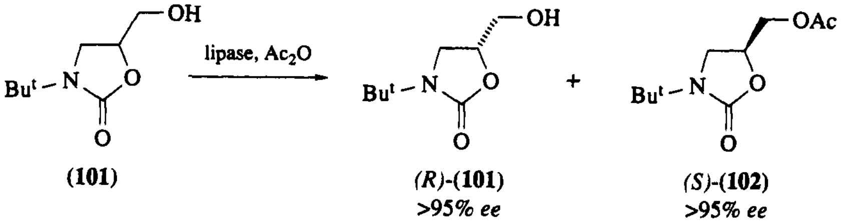
(37)

In contrast to the procedures described so far which all have to use a large excess of one component (ester in equations 33, 34 and 36, alcohol in equation 35 or acid in equation 37) direct enzymatic acylation with isopropenyl acetate or acetic anhydride[80] requires only stoichiometric amounts of the reagents (equations 38 and 39). Both acetate, **(100)** and **(102)**, and alcohol, **(99)** and **(101)**, are obtained with high enantioselectivity.



(38)



(39)

Enantiotopically selective ester hydrolysis can also be achieved enzymatically (Table 8). Either one ester group in a *meso*-diester **(103)**–**(106)** or one acetate in a *meso*-diacetate **(107)**–**(111)** are saponified with PLE or other lipases. In favorable cases enzymatic acylation and deacylation are stereochemically complementary and may thus be combined to gain access to both enantiomers, as illustrated by the example in Table 9.[89]

## 2.2.2 SYNTHESIS OF LACTONES

Lactones are intramolecularly formed esters of hydroxy carboxylic acids and may, consequently, be prepared by cycloacylating or cycloalkylating processes. The CGA intermediate **(116)** has to be formed from **(115)** by means of some activating agent, whereas cycloalkylation presupposes the carboxylate **(119)**, with some leaving group Y in the ω-position. Y may be an oxygen-leaving group (HGA mechanism) or a halogen. The most significant difference between cycloacylation and cycloalkylation is the retention and inversion of the configurations of the ω-center, respectively. Most lactonizations proceed *via* cycloacylation.

### 2.2.2.1 Synthesis of α-Lactones

α-Lactones have no significance in synthesis, but in their own right they are interesting, highly strained, and hence, transient species. Classical work has provided evidence that the hydrolysis of α-bromopropionic acid in mild base proceeds *via* **(121)**, which is then opened with inversion of configuration, so that the overall result is retention of configuration at the α-center.[90]

α-Lactones of type **(122)** may be generated photolytically in a frozen matrix and polymerize at higher temperature.[91]

### 2.2.2.2 Synthesis of β-Lactones

β-Lactones are normally stable compounds, which have found ample application as synthetic intermediates,[92] and, quite recently, have been detected as the central structural unit in physiologically active natural products like obaflorin **(123)**[93a] and lipstatin **(124)**.[93b] Characteristic applications of β-lactones in synthesis are the stereospecific $CO_2$ elimination to form di- and tri-substituted alkenes (*e.g.* from **125**; equation 40)[94] or Grignard addition to the carbonyl group (*e.g.* equation 41).[95] Particularly useful is the formation of β-lactone enolates **(126)**, which react with a variety of electrophiles (EX) with high stereocontrol (equation 42).[96] Organocuprates may be used in chain elongations to form β-branched carboxylic acids (equation 43).[97]

### 2.2.2.2.1 β-Lactones via cycloalkylation

It has been shown that β-bromocarboxylic acids like (**127**) and (**129**) cyclize with mild base to form β-lactones like (**128**; equation 44)[98] and (**130**; equation 45).[99] The reaction is mostly accompanied by fragmentation to the alkene, as shown by the conversion of (**131**) into (**132**) and (**133**) (equation 46).[100] In this particular example, only *trans*-β-lactone (**132**) was found, inspite of the *threo* configuration of (**131**), which indicates an $S_N1$- rather than an $S_N2$-type cyclization.

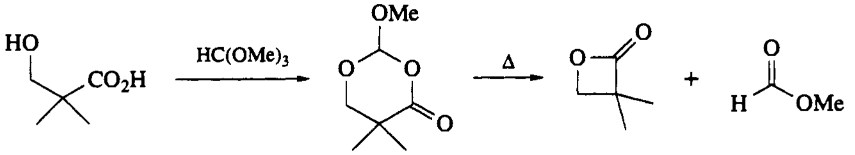
(131) R = Me, Et (132) 17% (133) 40%

(46)

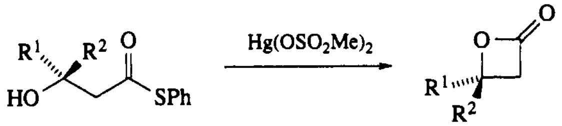
### 2.2.2.2.2 *β-Lactones* via *cycloacylation*

Cycloacylation of β-hydroxy carboxylic acids can be accomplished with various dehydrating agents. For example (**134**) has been converted into the δ-lactone acetal (**135**) with orthoformate. On heating, (**135**) loses methyl formate under formation of the β-lactone (equation 47).[101] β-Hydroxy thiol esters like (**136**) have been reported to form β-lactones under retention of configuration in high yields (equation 48).[102]



(134) (135)

(47)



(136)

(48)

The method of choice, however, is the reaction of (**137**) with benzenesulfonyl chloride in pyridine at low temperature (equation 49). This conversion proceeds *via* (**138**) with strict retention of configuration and is compatible with a variety of substituents (Table 10).[103] However, it fails for small substituents (**137l** and **137m**) in which case only polyesters are formed. In cyclic systems like (**140**) β-lactone formation cannot occur if the carboxy and the hydroxy functions are *trans* (equation 50) In this case the di-

sulfonated anhydride (**143**) is formed in *ca.* 40% yield, presumably *via* (**142**) as an intermediate.[104] Alkene formation is the main reaction for systems with strongly electron-donating substituents in the β-position (*e.g.* **137a**). Presumably these β-lactones are unstable and eliminate carbon dioxide very rapidly.[105]

### 2.2.2.2.3 β-Lactones from β-hydroxy carboxylic acids with HGA and CGA reagents

*(i) Mitsunobu conditions*

Under Mitsunobu conditions ('*anti*') *threo*-hydroxy carboxylic acids (**144**) form (*Z*)- and (*E*)-alkenes (**150**) and (**151**) and *cis*- and *trans*-β-lactones (**152**) and (**149**) in various ratios, depending on $R^1$ and $R^2$ (Table 11). The mechanism (Scheme 3) involves a competition between the HGA and CGA intermediates (**145**) and (**146**). For $R^2$ with a high +M effect (*e.g.* Ph, 2-thienyl *etc.*), the zwitterion (**147**) also has to be considered. After rotation to (**148**), intermediate (**145**) gives rise to the products (**151**) and (**152**). *Via* (**146**) the lactone (**149**) is generated. It is obvious from Table 11 that only large $R^1$ and $R^2$ groups lead to CGA (**144d** and **144i**), whereas the rest prefer the HGA pathway.[106]

### *(ii) Vorbrüggen–Eschenmoser conditions*

*Threo*-acids (**144**) react with DMF dimethyl acetal (**155**) at room temperature to give alkenes (**150**) and (**151**) along with the methyl ester (**159**) in varying ratios (Table 13). The mechanism (Scheme 5) suggests the initial formation of an ion pair (**156**) and (**157**), which either collapses to (**159**) (irreversibly) or (**158**) (reversibly). From (**158**) *E*1 and *E*2 fragmentations are possible, generating (**151**) and (**150**), respectively.[108] In general it may be stated that activating, *e.g.* aryl, substituents in the R$^2$ position are required for alkene formation. No β-lactones are formed from (**144**), quite in contrast to the '*erythro*' analogs (**153**) (Scheme 6 and Table 14), which react to (**149**), (**150**) and (**160**).[108] However, the overall yields of β-lactones (**149**) do not exceed 36% (**153g**).

#### 2.2.2.2.4 *β-Lactones* via *C—C connections*

Although C—C connecting reactions are discussed elsewhere in 'Comprehensive Organic Synthesis',[109] it may be mentioned that epoxides react regioselectively with carbon monoxide under rhodium catalysis (equation 51)[110] and benzyl bromides undergo carbonylation and subsequent lactonization under the influence of a $Pd^{II}$ catalyst (equation 52).[111] The [2 + 2] cycloaddition of ketenes to carbonyl compounds, catalyzed by Lewis acids, is a familiar route to β-lactones (equation 53).[112]

### 2.2.2.3 Synthesis of γ-Lactones

γ-Lactones are among the most abundant substructures in natural products.[113] This fact had kindled enormous activity in the field of γ-lactone synthesis.[114] γ-Lactones have been prepared by direct cycloacylation of γ-hydroxy acids, either as such or generated as transient intermediates, and by cycloalkylation, either of γ-halocarboxylates or of β,γ- or γ,δ-unsaturated acids by additions to the double bond.

#### 2.2.2.3.1 *γ-Lactones* via *direct cycloacylation of γ-hydroxy acids or derivatives*

As indicated in equation (54) γ-lactones may be generated from γ-hydroxy acids, esters or amides, generally under acid catalysis. For esters and amides also base catalysis is appropriate. The rate of cyclization varies with the degree of substitution along the carbon chain. Bulky substituents, particularly if they have to be arranged *cis* to each other during ring formation, retard the reaction. For example (**161**) takes several days at 25 °C (equation 55),[115] whereas (**162**) only requires 14 h to form the lactone (equation 56).[116]

The different rates of cyclization of the four diastereomeric hydroxy acids (**163**), (**165**), (**167**) and (**169**) have been utilized for separating (**163**) and (**165**) from (**167**) and (**169**). On treatment with dilute sulfuric acid in acetonitrile (**167**) and (**169**) spontaneously form the lactones (**168**) and (**170**), whereas (**163**) and (**165**) remain unchanged and can be cyclized only by treatment with acetic anhydride in pyridine (equations 57–60).[117]

In cyclic systems like (**171**), (**173**), (**175**) and (**177**) strain arguments are even more important. All four acids form the lactones only on heating to >130 °C, but the yields reflect the highly different ring strain encountered: the most favorable diequatorial lactone (**172**) is formed quantitatively (equation 61), whereas the strained diastereomers (**174**), (**176**) and (**178**) form reluctantly (equations 62–64).[118] The ring clo-

sure of (**179**) to the bridged lactone (**180**) requires prolonged heating with acetic anhydride (equation 65).[119]

Lactonization may sometimes be combined with deketalization, as shown by equation (66).[120] The γ-lactone is formed in preference to the δ-lactone, in analogy to related observations.[121] Transketalization is also shown by (**183**), which forms the β-anomer of (**184**) with >10:1 selectivity (equation 67).[59]

The examples in equations (68–70) demonstrate that unsaturated γ-lactones are also accessible by the usual cyclization. The case of (**185**) shows that again the five-membered lactone is preferred.[122] The (*E*)-

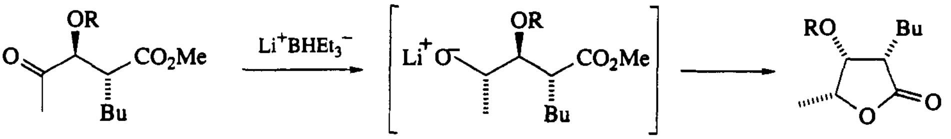
(72)

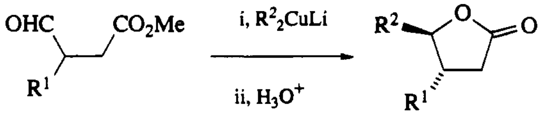
### 2.2.2.3.2 *γ-Lactones by* in situ *cyclization of γ-hydroxy carboxylic acid intermediates*

In this section sequences are described in the course of which γ-hydroxy carboxylic acid derivatives are formed and immediately cyclized to γ-lactones. For instance, γ-keto ester (**195**) is reduced with 'super hydride' to give the alkoxide ester (**196**) with 7:1 selectivity (equation 73); (**196**) cannot be isolated, due to the rapid formation of lactone (**197**).[125] Similarly, cuprates add to γ-aldehydo esters with high selectivity to form *trans*-4,5-disubstituted γ-lactones after acidification (equation 74).[126]



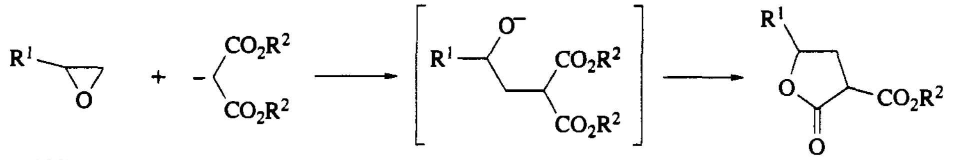
**(195)** R = COBu$^i$ **(196)** **(197)**

(73)



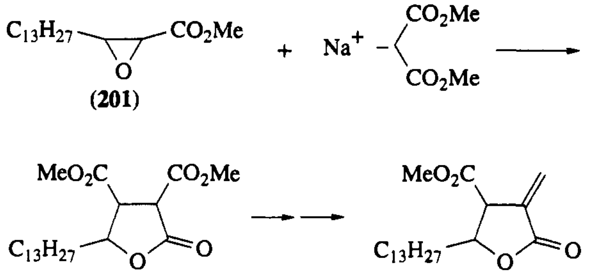
(74)

Another possibility is the addition of malonate anions to epoxides (equation 75), which, *via* the alkoxide ester (**199**), deliver the lactone ester (**200**) immediately.[127] This concept has been used in the nonstereocontrolled synthesis of protolichesterinic acid ester (**203**) from (**201**) *via* (**202**; equation 76).[128]



**(198)** **(199)** **(200)**

(75)



**(201)** **(202)** **(203)**

(76)

Instead of malonic esters the lithium dianions of carboxylic acids may also be used, as shown by equation (77).[129] Enantioselective γ-lactone formation has been achieved by Meyers as a ramification of his well-known oxazoline alkylations. As illustrated by equation (78), (**206**) is deprotonated and alkylated with ethylene oxide to give (**207**), which in a second alkylation step furnishes (**208**) diastereoselectively. The oxazoline ring so far has served as a carboxy synthon. Unmasking with acid immediately generates the α-substituted optically active γ-lactone (**209**).[130]

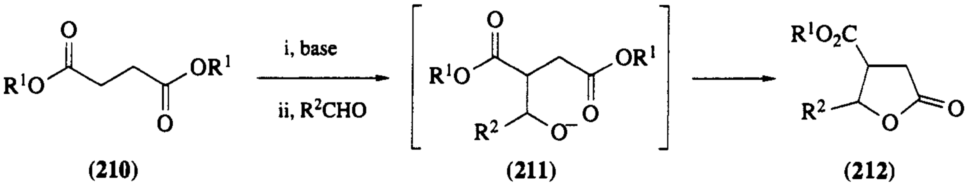
Instead of epoxides carbonyl compounds may be used as electrophiles to generate the γ-hydroxy carboxylic acid intermediate. In the classical Stobbe reaction (equation 79) succinic esters are deprotonated and treated with aldehydes or ketones to form, *via* the unstable adduct (**211**), the paraconic ester (**212**).[131]



(210)
i, base
ii, R2CHO
(211)
(212)

(79)

A more recent and stereocontrolled version of the Stobbe reaction is shown in equation (80). β-Lactone ester (**213**) is deprotonated to the enolate (**214**), which adds aldehydes to give either monocyclic

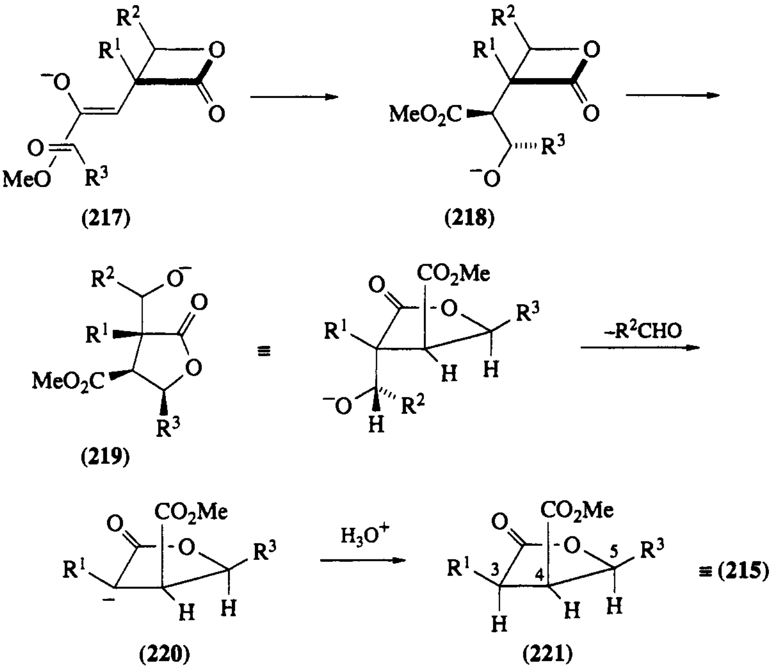
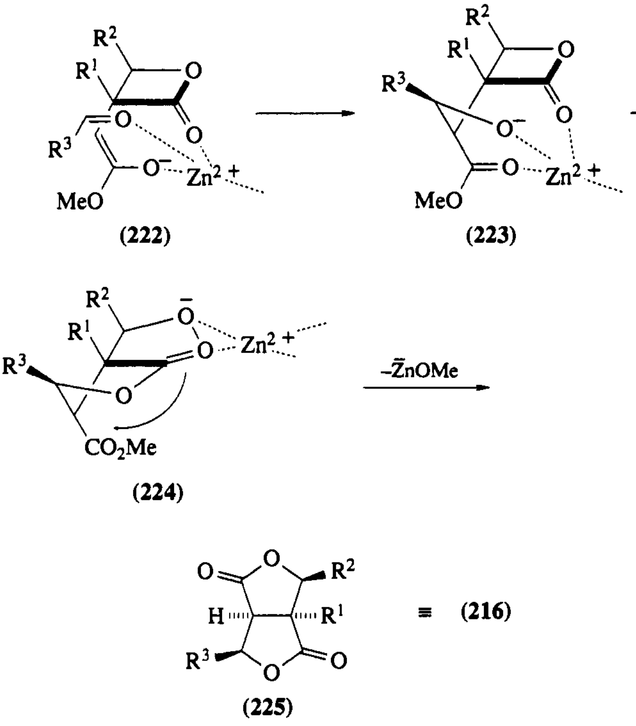
(80)

paraconic esters (**215**) or bicyclic γ-lactones (**216**). In the presence of HMPA (**215**) is formed preferentially, and in the presence of zinc(II) chloride (**216**) is formed (preferentially), in both cases with a high degree of stereocontrol.

A mechanistic rationalization is given in Scheme 7 (HMPA additive) and Scheme 8 ($ZnCl_2$ additive) respectively. In both Schemes analogous adducts (**218**) and (**223**) are formed stereoselectively, which rearrange to the γ-lactone alkoxides (**219**) and (**224**). In the presence of HMPA, retroaldol cleavage to



**Scheme 7**



**Scheme 8**

(**220**) occurs, and after protonation (**221**) is formed. In the presence of the chelating Zn ion, by contrast, a second lactone ring is closed between the ester group and the alkoxide anion, generating (**225**).[125]

Similar condensations can be accomplished with other types of stabilized carbanions, *e.g.* sulfonyl anions, as illustrated by equation (81). The resulting sulfonyl lactone (**228**) eliminates sulfinic acid on treatment with *p*-TsOH to furnish the α,β-unsaturated system (**229**).[132] Spirolactonization is the result of the Reformatsky reaction of ester (**231**) with cyclic ketones.[133] In equation (82), this reaction is applied to the synthesis of the lysergic acid precursor (**232**), which is formed stereoselectively from (**230**).[134]

A carbocyclic ring and a γ-lactone may be created in a concise manner by using the Sakurai cyclization of (**233**) to (**234**) and closing the lactone in the usual manner under acid catalysis (equation 83).[135] The C—C connection required to generate the γ-hydroxy carboxylic acid may be performed by means of a pericyclic arrangement. For instance, the allylic alcohol (**236**) reacts with an orthoester to form, *via* (**237**), the hydroxy ester (**238**), which cyclizes under the conditions to (**239a**). For unsymmetrically substituted alcohols (**236**), the regioisomer (**239b**) is also formed in comparable amounts (equation 84).[136]

γ-Lactones may be the result of an oxidative cyclization of 1,4-butanediol derivatives (**240**). On treatment with silver carbonate on Celite (Fetizon's reagent) (**242**) is formed, presumably *via* lactol (**241**) (equation 85).[137] A lactol–lactone oxidation is the ultimate step in a rather complex sequence (equation 86). Cyclopropane ester (**243**) may undergo aldol-type additions to give (**244**), which on fluoride treatment opens the cyclopropane ring and gives first the aldehyde (**245**) and then the lactol (**246**). PCC oxidation leads eventually to the paraconic ester (**247**). Although a high degree of substitution is available, the stereocontrol is low.[138]

### *2.2.2.3.3 γ-Lactones via cycloalkylation*

There are numerous variations of cycloalkylating lactone formations. They may be classified into HGA ring closure of γ-hydroxy acids or esters, $S_N2$ ring closure of γ-bromocarboxylates, lactonizations under participation of alkenic double bonds or γ-lactone formation by carbenium rearrangements.

### *(i) HGA lactonization of γ-hydroxy acids*

Such cases are extremely rare, as the normal mode of action involves CGA mechanisms. However, Trost *et al.* have shown (equation 87) that in cases where the normal CGA reaction is prohibited due to ring strain, HGA ring closure under Mitsunobu conditions may be accomplished, *e.g.* from (**248**) to (**249**).[139] In contrast, hydroxy acid (**250**) has been found to undergo CGA ring closure to (**251**) spontaneously, as well as under Mitsunobu treatment. However, HGA reactions can be accomplished (equation 88) by preparing the mesylate (**252**) with sulfene, and by subsequent $S_N2$ cyclization with base to form (**252**).[140] An acid-catalyzed HGA lactonization has been reported for the hydroxypyrrolidines (**254**) and (**256**), both of which, under acid treatment, form the lactone (**255**), presumably *via* (**257**; equation 89).[141]

## *(ii) γ-Bromo carboxylates*

γ-Lactones may be obtained from (**258**) with strong base (equation 90). The reaction may be reversed by ring opening with hydrobromic acid, which is by far the more important process. The inversion of configuration on ring closure is demonstrated by means of the cyclic derivative (**259**; equation 91).[142]

*(iii) γ-Lactonization of unsaturated carboxylic acids*[143]

Usually γ,δ-unsaturated acids (**260**) are employed in these lactonizations. The initial step involves an electrophilic attack at the double bond, either by a proton or a reagent X—Y (**264**). An activated species (**261**) is thus generated, suitable for the nucleophilic addition of the carboxy group, which in principle may close to a six- or five-membered lactone ring (**263** or **262**; equation 92). Normally, (**262**) is preferred on the basis of vector approach analysis.[144]

trol remains unclear. The malonic esters (**269**)[147] are decarboxylated after lactonization. The enyne acid (**271**) is lactonized at the triple bond without affecting the alkenic moiety (equation 96).[148]

Hydroxylactonizations (equations 97–99) involve the formation of a stable and, in general, stereochemically defined epoxide intermediate with peroxy acids. In an ensuing step these epoxides are cyclized with acid catalysis under the participation of the carboxylic group. If steric reasons prohibit ring closure, as in equation (98), the diol acid (**278**) is formed instead of the hydroxy lactone (**275**).[149] Equation (99)[150] shows an example for the stereocontrol of the epoxidation step by an axially oriented carboxy group, which is then in an appropriate position to close the lactone ring (**281**).

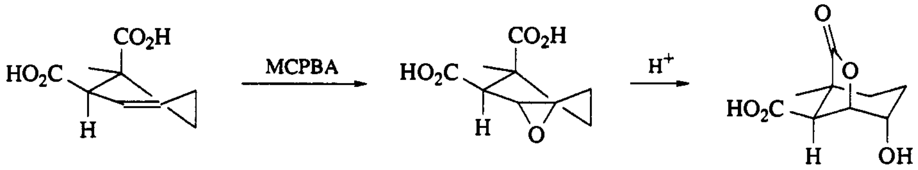
**(276)** **(277)** **(278)**

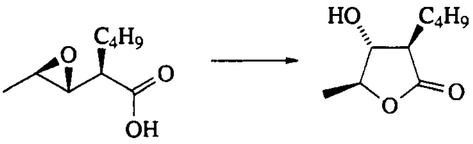
(98)



**(279)** **(280)** **(281)**

(99)

Equation (100)[116] illustrates the lactonization of a β,γ-epoxy acid. Only the γ-lactone (**283**) is formed, with inversion of configuration.



**(282)** **(283)**

(100)

Halolactonizations have been used extensively for achieving high degrees of functionalization in a regio- and stereo-controlled manner.[151] The conversion of (**284**) into (**285**; equation 101)[152] is a key step in Corey's prostaglandin synthesis to prepare the central intermediate (**286**). For β,γ-unsaturated acids like (**287**) the β-lactone (**288**) is formed under kinetic control, which then equilibrates to the γ-lactone isomer (**289**; equation 102).[153]

In acyclic systems like (**290**) the facial selectivity of the double bond addition may be directed by a free OH function (Scheme 9).[154] It can also be shown that the regiocontrol depends on the reagent. Mercurilactonizations (equation 103)[155] are related to halolactonizations. The C—Hg bond may be cleaved reductively by a radical process.

### (iv) *γ-Lactones* via *rearrangements*

Under MgBr$_2$ catalysis β-lactones like (**296**) rearrange to γ-lactones (**297**) under dyotropic migration of an alkyl or hydrogen substituent (equation 104).[156] The stereochemistry as shown in the stereoformulae (**302**) and (**303**) requires an antiperiplanar arrangement of the migrating groups. In cyclic systems spiroannulation and angular annulation may be achieved, depending on the ring sizes (equations 105 and 106).[157]

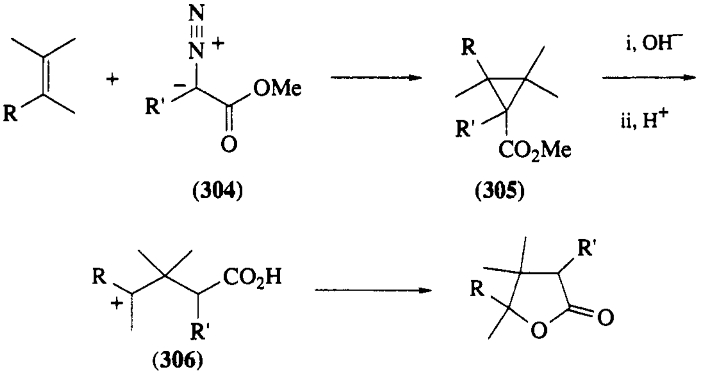
**(302)** **(303)**

An interesting and potentially useful sequence is shown in equation (107). Cyclopropane esters (**305**) may be prepared by the addition of diazo esters (**304**) to double bonds under elimination of nitrogen. After saponification the acid is *O*-protonated to open the cyclopropane ring, and the resulting carbenium ion (**306**) is trapped by lactonization. In effect a γ-lactone has been annulated to a double bond in a regiodefined manner.[158–160] Examples are given in Scheme 10. A related reaction involves the conversion of the cyclopropane ester (**307**) into the lactone (**308**; equation 108).[161]



**(304)** **(305)** **(306)** (107)

### 2.2.2.3.4 *γ-Lactones* via *carbonylation of homoallylic alcohols*

It has been shown recently[162] that homoallylic alcohols (**309**) undergo regiocontrolled carbonylation–lactonization to form (**310**) or (**311**) in good yield (equation 109). In the reaction of *cis*-3-hexenol, (**315**) is formed as a side product to (**313**), presumably *via* the isomerization of intermediate (**312**) to (**314**) (Scheme 11).

A direct way to α,β-unsaturated γ-lactones involves the Pd-catalyzed carbonylation of *cis*-vinyl iodides (**316**; equation 110).[163] In a similar way *exo*-methylene lactones[319] may be prepared from the alkynols (**318**; equation 111).[164]

### 2.2.2.3.5 *γ-Lactones from furans*

A fundamentally different route to unsaturated lactones involves the oxidation of furanes (*e.g.* **320**) with NBS and subsequent debromination with Zn to give the butenolide (**321**; equation 112). The alternative regioisomer (**323**) may be prepared by using MCPBA as the oxidant to furnish the hydroxy lactone (**322**), which is then reduced to (**323**; equation 113).[165]

### 2.2.2.4 Synthesis of δ-Lactones

The methods applied for the synthesis of δ-lactones are very similar to those described for γ-lactones. In general, the tendency to form a six-membered ring is slightly lower than that for γ-lactonization. This is illustrated by equation (114); δ-hydroxy esters polymerize on acid treatment. Depolymerization takes place on heating, and the δ-lactone is formed.[166] Strained δ-lactones may be closed using acetic anhydride activation (**324**; equation 115),[119] whereas transannulations to decalin systems readily occur on heating (equation 116).[118] δ-Lactones can be efficiently prepared by glycol cleavage of 1,2,6-triols (**326**; equation 117). The lactol (**327**) is oxidized to (**328**) with PCC.[167]

Meyers' approach to α-chiral lactones may be expanded to the δ-lactone series with *ee* values comparable to those achieved for lactones (equation 118).[168] Mercuri- and similarly halo-lactonizations of δ,ε-unsaturated carboxylic acid derivatives are an efficient way to achieve stereocontrolled heteroatom–carbon ring closure, *e.g.* of (**333**) to (**334**; equation 119).[143]

An interesting case of a δ-lactonization under inversion of configuration has been reported by Prasit and Rockach (equation 120).[169] Triol ester, (**335**), with a good leaving group in the terminal position undergoes a Payne rearrangement to (**336**) and (**337**) with aqueous base, and (**337**) cyclizes to form (**338**). As in the γ-lactone series, lactonization may be preceded by a C—C connecting process. For instance, as shown in equation (121), enamine alkylation generates a δ-keto ester, which after saponification, reduction and acidification delivers the δ-lactone.[170]

### 2.2.2.5 Enantioselective Lactonization

Much attention has been devoted to asymmetric lactonization of *meso*-hydroxy acids. In the case of 4-hydroxypimelate (*S*)-camphorsulfonic acid [(*S*)-CSA] has been found to deliver a proton enantioselectively to the *pro-R* appendage. In this way lactone (**340**) is generated with 94% *ee* (equation 122).[171] A different approach has been used in the case of (**341**). An axially chiral binaphthylamine is used as an auxiliary for forming the dimamide (**342**), which is hydrolyzed enantioselectively to the mono amide (**343**). In this way an optically active lactone is created, which is removed from the auxiliary by acylation of the free amino group, and reduction of the amide to form (**344**). To secure the configuration and the optical purity, (**344**) was converted into the known derivative (**345**; equation 123).[172]

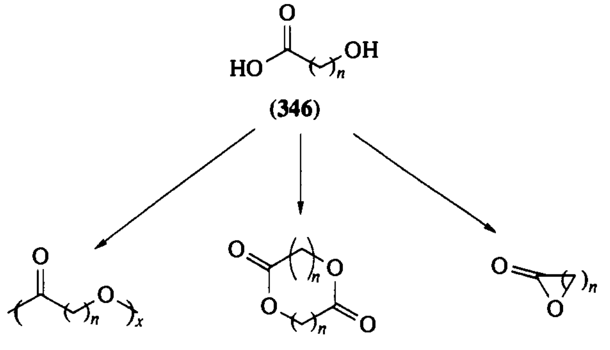
## 2.2.2.6 Macrolactonization

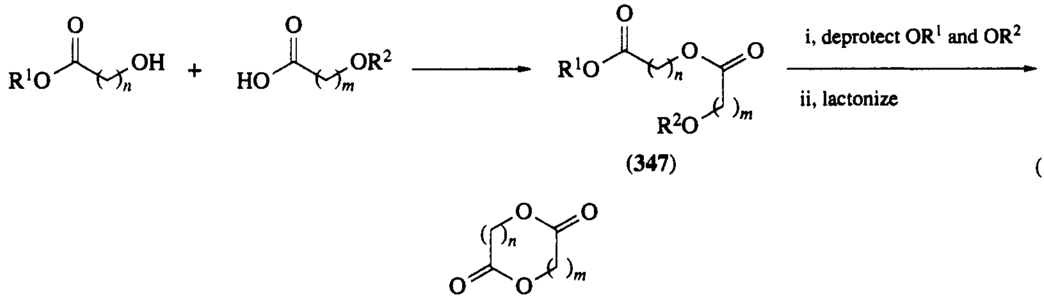
The synthesis of lactones with ring sizes of more than nine (macrolides) has been one of the central objectives in the past 10 years.[173] In most cases these syntheses involve the construction of an acyclic ω-hydroxy carboxylic acid ('seco-acid') by a number of C—C connecting steps, which eventually is submitted to the lactonization process proper. After the lactonization, some deprotecting steps have to follow to establish the desired functionality. For the lactonization essentially the same methods are used as those described in Section 2.2.1 for esterifications. The crucial problem, however, in lactonizing a seco-acid (**346**) is to avoid polymerization and to direct the reaction either to a monomeric (macrolide) or a dimeric ('diolide') lactone. Polymerization in general can be overcome, to a certain degree, by employing high dilution conditions. The dichotomy of macrolide *versus* diolide can be influenced by the proper choice of the reagent; for instance, Mitsunobu conditions preferentially lead to diolides, whereas most other reagents induce macrolide formation (Scheme 12).



**(346)**

**Scheme 12**

A controlled way to achieve diolide formation is the application of protecting groups for the hydroxy function of one hydroxy acid moiety and the carboxy group of the other and thus to prepare a seco-acid (**347**) by esterification (equation 124). After deprotection, (**347**) may be lactonized to the diolide. In macrolactonization one encounters frequently the situation that the seco-acid has more than one hydroxy group suitable for ring formation. To avoid lactones of undesired ring sizes, protective groups have to be attached to the unwanted positions in course of the synthesis of the seco-acid which are stable under the lactonization conditions, and can be removed without destroying the lactone ring. In the following discussion the subdivisions follow the reagents employed for lactonization rather than the target structures envisaged. As for the esterifications one may distinguish macrolactonizations with retention of configuration (cycloacylations) or inversion of configuration (cycloalkylation). It will be noted that for one and the same seco-acid type, different lactonizing agents have been used, which suggests that the choice of these reagents has been made according to the personal taste and experience of the individual author, and not following a deeper rationale.



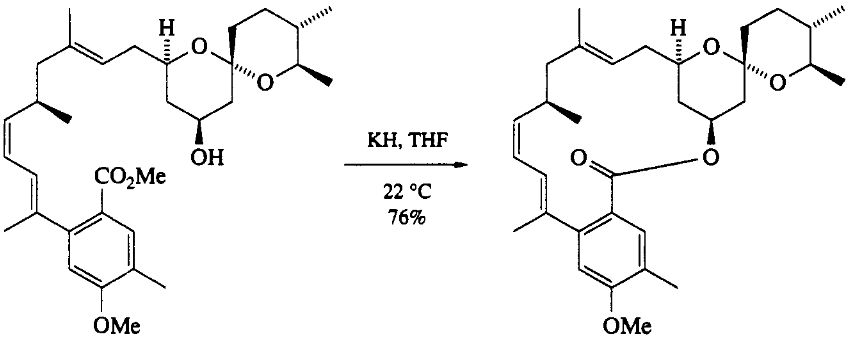
**(347)** (124)

**(348)** Diolide

### *2.2.2.6.1 Cycloacylating macrolactonization*

*(i) Macrolactonization of hydroxy esters under base catalysis*

The simplest way of macrolactonization is the use of acid or base catalysis so that after the ring closure no tedious separation of the lactone from auxiliary by-products is required. However, there are only very few such examples. The 16-membered macrolide ring of milbemycin β3 is closed very efficiently by simply treating the hydroxy ester (**349**) with potassium hydride. OH deprotonation induces ring formation with retention of configuration to (**350**; equation 125).[174]



**(349)** **(350)** (→ Milbemycin $\beta_3$) (125)

*(ii) Macrolactonization with mixed anhydrides*

The formation of mixed anhydrides, which in some cases may be isolated, is an established method. For instance, racemic zearalenone (**352**) has been obtained by treating the seco-acid (**351**) with trifluoroacetic anhydride (equation 126).[175] Similarly, antimycin $A_3$ has been prepared.[176] A more modern procedure makes use of Yamaguchi's 2,4,6-benzoyl chloride esterification.[26] For example, a synthesis of methynolide is based on the lactonization of the alkynic seco-acid (**353**) to (**354**; equation 127).[177]

(→ Methynolide)

A more complex hydroxy acid is lactonized in a synthesis of (9*S*)-9-dihydroerythronolide A, albeit in low yield (equation 128).[178] By acid treatment (**356**) is deprotected to give the desired target molecule. The presence of $sp^2$-centers in the seco-acid obviously facilitates lactonization, as shown by the preparation of the mycinolide V precursor (**357**; equation 129).[179] A mixed carbonate is used in the synthesis of the tylonolide precursor (**358**; equation 130).[180] In general, DMAP catalysis is helpful in the ring closing step in most cases.

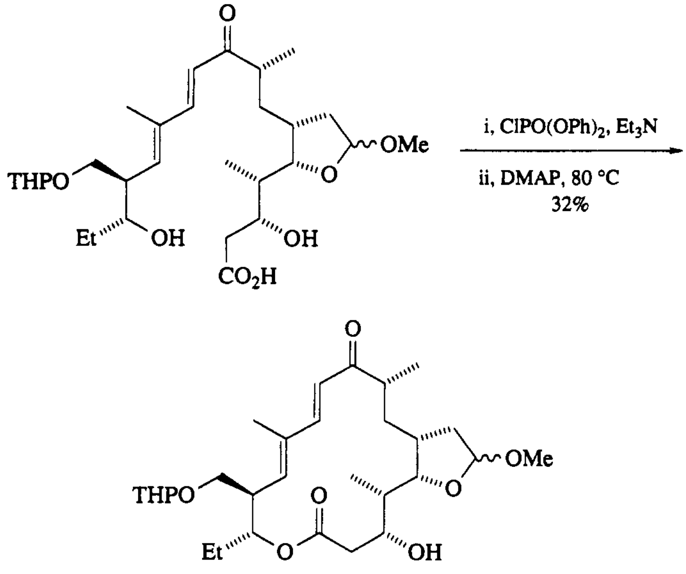
*(iii) Thiol ester mediated macrolactonization*

Although thiol esters are not common for normal esterifications they have found ample application in macrolactonization. Thus, the Corey–Nicolaou procedure which uses Mukaiyama's preparation of 2-thiopyridyl esters *via* a redox condensation[181] is one of the most general and efficient macrolactonization methods described so far. By forming a chelate hydrogen bridge double activation is achieved to facilitate the conversion of the activated ester (**359**) into the tetrahedral intermediate (**360**), which eliminates thiopyridone to form the lactone (equation 131).[182] The method has been applied to the syntheses of zearalenone (*via* **361**),[182] brefeldin A (*via* **362**),[183] tylonolide (*via* **363**),[184] and (+)-18-deoxynargenicin $A_1$ (*via* **364**) (note that no protective groups are necessary for the OH on ring c).[185]



**(358)**
(→ Tylonolide)

(130)

In all cases, the indicated *O*-acyl bond is closed following Corey's original procedure.[182] In the case of the vermiculine precursor (**365**) diolide formation to (**366**) is observed (equation 132).[186] To meet the special requirements of his erythronolide A and B syntheses Corey developed a diimidazolyl disulfide (**367**) by which (**368**) is obtained from the seco-acid in acceptable yields.[187] The same reagent has been used in a recent synthesis of erythronolide B (*via* **369**).[188a] Gerlach has found that silver(I) ions drastically enhance the rate of the lactonization,[188b] presumably by forming a silver–thiol bond in the activating complex. Masamune also has resorted to thiol ester activation in his macrolide syntheses. In contrast to Corey he used the *t*-butyl thiol esters (*e.g.* **370**), which are lactonized under treatment with copper(I) triflate to remove the thiol, and Hünig's base to abstract the OH proton. In this way a respectable yield of

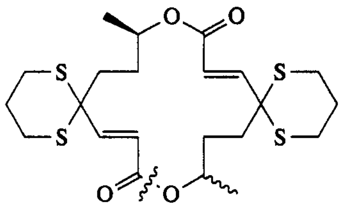
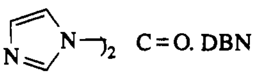
### *(iv) Macrolactonization* via *activated amides*

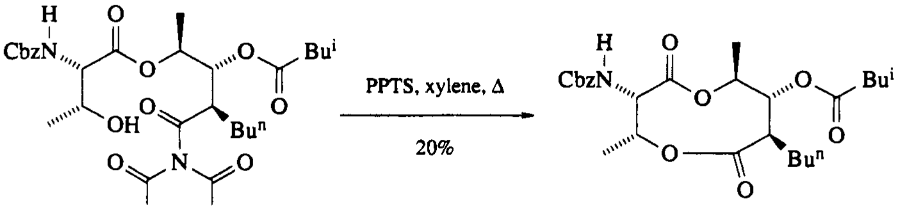
Staab's *N*,*N*-carbonyldiimidazolide method has been applied in a synthesis of pyrenophorine (*via* **373**), in which the indicated bond has been closed.[191] More recently, the usual activated amide (**374**) has been used to obtain the *N*-protected antimycin A3 derivative (**374**) under acid catalysis (equation 134).[192]



**(373)**



(→ Pyrenophorin)



(134)

**(374)** **(375)**

### *(v) Macrolactonization* via *activated esters*

DCC coupling serves in Stork's erythronolide A synthesis for closing the lactone (**376**) at the indicated C—O bond.[193] A modified DCC-type reagent (**378**) was successful in the preparation of the milbemycin β3 precursor (**377**).[194] The resulting urea derivative is water soluble and can thus be easily separated from (**377**) during work-up. An interesting enol ester type activation has been devised by Gais *et al.* to prepare the brefeldin A precursor (**383**; equation 135).[195] The hydroxy acid (**379**) adds the carboxy oxygen to the triple bond of the ynamine ketone (**380**) to form the enol ester (**381**), which spontaneously forms (**382**) *via* a 1,5-acyl migration in 96% yield. Under acid catalysis (**382**) lactonizes to (**383**).

Mukaiyama's 2-halopyridinium activation has also been applied to macrolactonization, to prepare, for instance, the brefeldin A intermediates (**384**)[196] and (**385**).[197] In a very elegant synthesis of (+)-aspicilin the macrolactonization has been performed with the aid of a hydroxy ketene intermediate (**387**), which had been generated *in situ* by the photolytic ring opening of (**386**). The primary macrolide (**388**) is then converted into (**389**) by elimination of sulfinate and acetyl azide (equation 136).[198] A cyclic alkoxy stannylene carboxylate (**391**) has been employed in a number of model macrolactonizations leading to nodusmycin, ingramycin and others (equation 137).[199] Compound (**391**) is readily formed from the hydroxy acid (**390**) and Bu2SnO. As in Corey's method, intramolecular hydrogen bridging is postulated to effect double activation.

### *2.2.2.6.2 Cycloalkylating macrolactonization*

The Mitsunobu procedure has found considerable application, so it has been used for diolide formation in pyrenophorin (equation 138)[200] and colletodiol[201] syntheses. Yamaguchi's method[26] is much inferior.[202] As expected, the ring closure in equation (138) proceeds with inversion of configuration. In a

(139)

### 2.2.2.6.3 *Enzymatic macrolactonization*

So far, enzymatic macrolactonizations are on a model stage yet. Sih has tested the enantio- and diastereo-selectivity in the diolide formation from racemic (**395**). With lipase, high enantiomer selection in favor of the (*R*,*R*)-(**396**) has been observed, whereas the diastereoselection is disappointingly low (equation 140).[205]

## 2.3.1 AMIDES

The chemistry of amides has a long history, and since the end of the last century a plethora of synthetic methods has been developed.

The occurrence of the amide group in important technical polymers (*e.g.* polyacrylamides, nylon polyamide), in drugs (*e.g.* β-lactam antibiotics), in peptides and proteins has stimulated research leading to safe, simple, and in the case of α-asymmetric carboxylic acids nearly racemization-free, condensation methods.

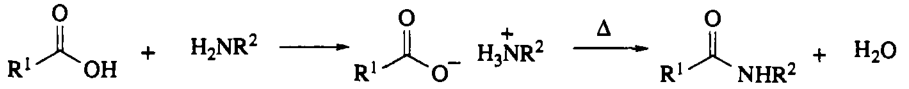
The synthesis of amides was recently reviewed by several authors. Short contributions came from Smith,[1] and Millar and Springall.[2] Especially due to practical aspects, those by Beckwith,[3] Challis and Challis,[4] Sandler and Karo,[5] and Döpp and Döpp[6] are more detailed.

With respect to peptide chemistry, Wünsch[7] discussed the scope and limitations of nearly all known procedures, and Merrifield and Barany[8] reviewed the application of several methods to solid phase peptide chemistry.

## 2.3.1.1 Carboxylic Acids and Amines

### *2.3.1.1.1 Dehydration of ammonium salts*

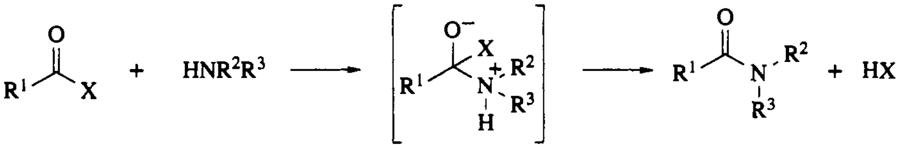
With simple carboxylic acids and amines, direct conversion to amides takes place at elevated temperatures (equation 1).[9] Generally, this reaction may be catalyzed by acid[10] or by cation exchange resin.[11] Addition of ammonium carbonate or urea[12] as a source of ammonia reduces reaction temperatures and improves yields.



(1)

### *2.3.1.1.2 Activation of the carboxy group (acylation of amines)*

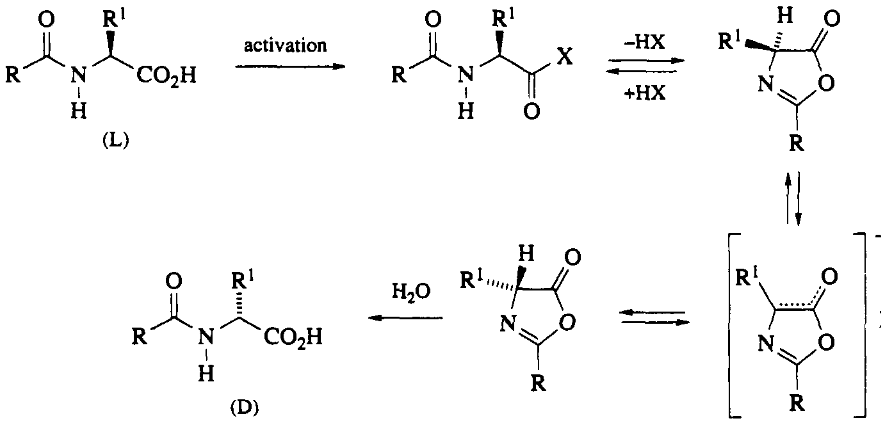
This is the most useful method of amide formation (equation 2). An activated carboxylic acid acylates ammonia, primary or secondary amines by a formal $S_N2$ substitution of leaving group X. The reactivity of the acylating reagent depends on the acidity of HX, and therefore the order of reactivity is RCOHal > $(RCO)_2O \approx RCON_3 > RCO_2R > RCONH_2 > RCOR$. Moreover, the reaction rate increases with higher nucleophilicity of the amine as well as base or acid catalysis.



(2)

In the case of peptide synthesis one always has to take the double functionality of α-amino acids into account. Therefore, protection of one of these groups is necessary to direct peptide bond formation to a defined product. Moreover, the protection group has to be stable against the peptide bond-forming reaction and should be easily cleaved to generate an appropriate functional group for the next coupling.

With the exception of glycine, all proteinogenic α-amino acids are chiral. The prevention of racemization in the case of the most commonly used α-protected amino acids is a prerequisite of successful peptide synthesis. *N*-acylamino acids might lose their stereochemistry according to the mechanism shown in Scheme 1. The proper choice of the protection group (*e.g.* urethane-derived), activation method and additives has to be made carefully.

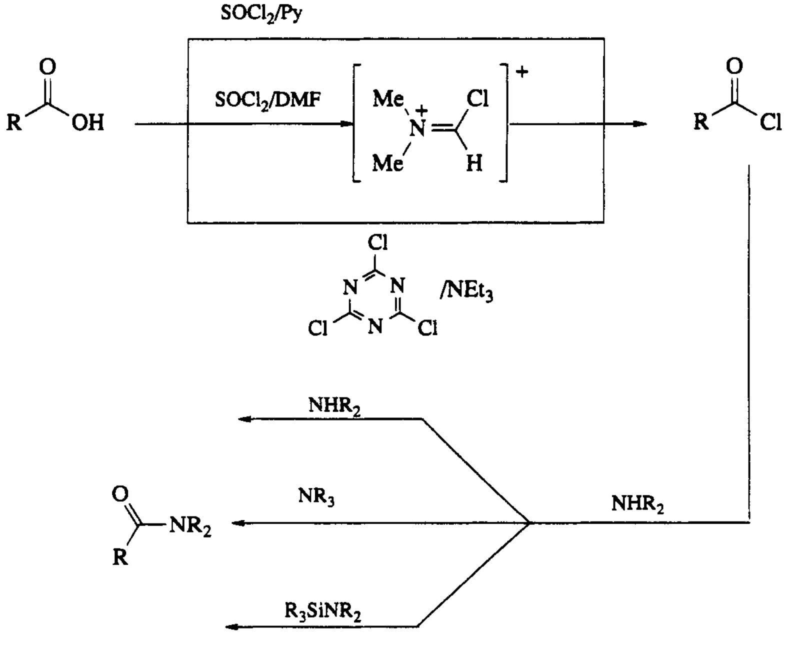


Scheme 1

Though the amide (peptide) forming reaction may be carried out by the use of hundreds of reagents and procedures, it is advisable to concentrate first on the most often applied reagents and conditions published in the literature. A further advantage is that these reagents are mostly commercially available.

### *(i) Carboxylic acid halides*

Activation of the carboxylic acid can easily be accomplished by the classical thionyl chloride method.[13,14] To generate acid chlorides under mild conditions without the evolution of gaseous HCl the reaction is carried out in $SOCl_2$/DMF[15] or started with the dicyclohexylammonium salt of the carboxylic acid.[16] Addition of DMF accelerates the reaction.[17] An imide chloride is considered to be the reactive species (Scheme 2). Other methods include activation with cyanuric chloride[18] or triphenylphosphine/tetrachloromethane.[19,20]



**Scheme 2**

Conversion to the corresponding amides with ammonia, primary or secondary amines proceeds by adding two equivalents of amine (to trap excess hydrogen chloride),[21] refluxing with one equivalent of amine in aromatic solvents,[22] or reacting with dialkylaminotrimethylsilane[23] under formation of the volatile trimethylchlorosilane. The latter method has advantages especially in the preparation of sterically hindered amides like acetic acid *t*-butylamide.[24]

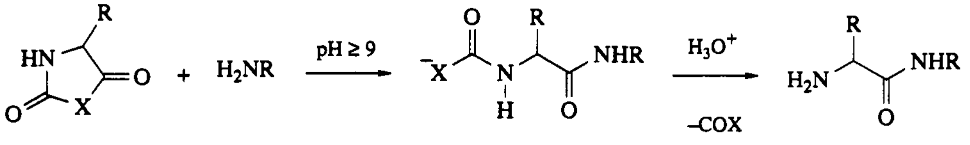
For peptide chemistry, protected amino acid chlorides are too highly activated and therefore not used due to their racemization tendency, reactions with amino acid side chains (*e.g.* asparagin), loss of selectivity against nucleophiles and the formation of internal Leuchs' anhydrides.[25]

Carboxylic acid fluorides are more stable to water and other nucleophiles. They are readily prepared by the use of cyanuric fluoride and converted to amides by silylated amines.[26] In contrast to the chlorides, protected amino acid fluorides exert virtually no racemization in peptide coupling.[27]

### *(ii) Carboxylic acid anhydrides*

#### *(a) Intramolecular.*

The preparation and use of α-amino-*N*-carboxylic anhydrides (NCA) and α-amino-*N*-thiocarboxylic anhydrides (NTA) for peptide synthesis was recently reviewed.[28] The main advantage of this coupling method lies in its simplicity. Protection of the nitrogen and activation of the carboxy group are achieved in one step (equation 3). NCAs (X = O) are prepared by the method of Leuchs, starting with *N*-substituted oxycarbonyl amino acid halides[29,30] and subsequent cyclization, or by the method of Fuchs–Farthing,[31,32] condensing the parent amino acid with phosgene. An alternative procedure that avoids gaseous phosgene uses trichloromethylchloroformate (TCF)[33] at elevated temperatures with a drastic reduction of reaction times. The preferred method of preparing NTAs (X = S) starts with *N*-alkoxythiocarbonyl amino acids and cyclization with $PBr_3$ at low temperature.[34–36] Alternatives starting with amino acid thiocarbamates or α-amino thioacids are more tedious and necessitate additional steps resulting in lower yields. Both NCAs and NTAs can be obtained in moderate to good yield with an optical purity exceeding 98% *ee*.



(3)

X = O (NCA); X = S (NTA)

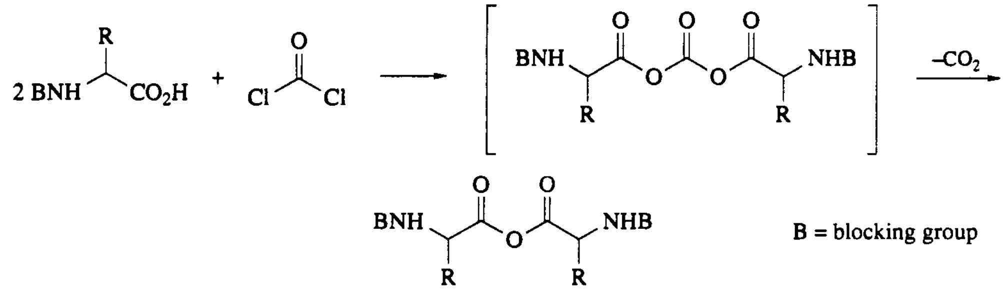
For peptide coupling, only lysine and cysteine have to be protected in their side chains. In NCA couplings, reaction parameters have to be carefully controlled:[37] rapid mixing, temperature (*ca.* 0 °C) and pH (optimum pH 10.2). Under these conditions racemization is virtually absent. In the case of NTAs, the coupling pH is lower (pH ≈ 9) and the overall yield is somewhat higher. Due to their generally higher racemization tendency, only the use of glycine-, alanine- and histidine-NTA is recommended in comparison to the NCAs.

The NCA/NTA technology has found application in the synthesis of fragments of ribonuclease A,[38] as well as in the large scale synthesis of ACE inhibitor precursors of enalapril[39,40] and the artificial sweetener aspartam.[35]

*(b) Intermolecular symmetric.*

Symmetrical anhydrides are prepared according to reactions reviewed in Chapter 2.1 of this volume. Advantageously, in contrast to unsymmetric anhydrides nucleophilic attack on both possible carbonyls gives the correct product. The disadvantage is the waste of one equivalent of carboxylic acid (which will be recovered in the case of expensive protected amino acids). The most widely used is acetic anhydride,[6] which acetylates amines under mild conditions.

In peptide chemistry two methods are used frequently. The reaction of phosgene with protected amino acids leads to symmetric anhydrides (equation 4), after disproportionation and release of carbon dioxide, which can be readily used to build up a growing peptide chain.[41,42] More recently, symmetrical amino acid anhydrides have been generated by carbodiimides like DCC,[43,44] water soluble carbodiimide[45] and diisopropylcarbodiimides[46] *in situ*. They are extensively applied to automated solid phase peptide synthesis. Attention has to be paid to the proper solvent system, as aprotic dipolar solvents tend to slow down reactions and increase formation of side products.[43]



B = blocking group (4)

*(c) Intermolecular mixed from* C*-acids.*

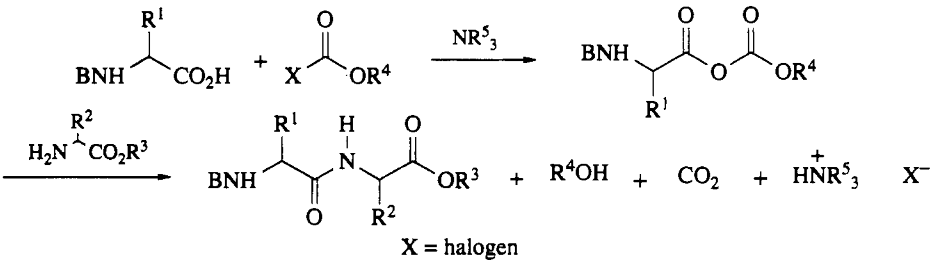
In mixed anhydrides, the difference between the two carbonyl groups with respect to their electrophilic character should be pronounced.

Formylation of amines is performed with formic acid/acetic acid anhydride.[47] The application of other mixed anhydrides with acetic acid as well as benzoic acid[48] is less favorable, because both possible amides will form in varying amounts.

An improvement resulting in a decreased amount of the second acylation product is the introduction of mixed anhydrides with α-branched carboxylic acids like isovaleric[49] and pivalic acid,[50] due to deactivating electronic and steric effects.

In peptide chemistry, activation with pivalic acid mixed anhydrides allows condensation with α-alkyl-α-amino acids (*e.g.* Aib),[51] *N*-methyl-α-amino acids[52] (resulting in the total synthesis of cyclosporin A) and Boc-Asn.[53]

Mixed anhydrides of carbonic acid half esters contain an activating carbonyl group with reduced electrophilic character (due to lone pairs of electrons on the vicinal oxygen atom) and are rapidly amidated by amines. The anhydride is formed at low temperature in the presence of tertiary amines (equation 5).



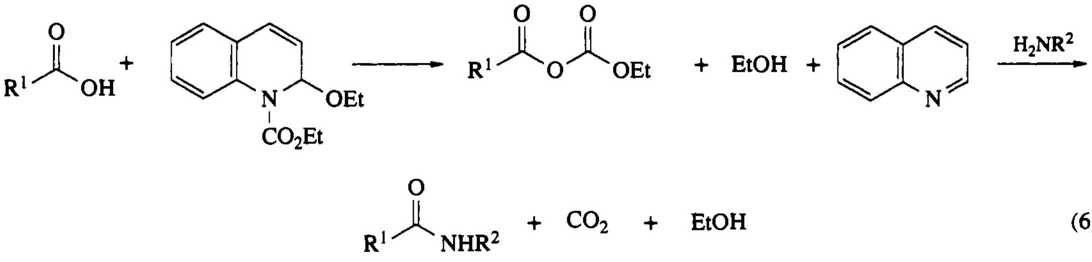
(5)

Isobutyl chloroformate is most frequently applied in peptide chemistry,[54–56] followed by ethyl chloroformate (see Table 1).[57] The advantage of this method is that the mixed anhydride does not have to be isolated, and during work-up only carbonic acid half esters are formed, which decompose to an alcohol and carbon dioxide. Only in the case of sterically hindered amino acids does the opening of the anhydride at the undesired carbonyl occur in considerable amounts. Furthermore, short activation times (30 s) at low temperatures lead to peptides with minimal racemization.[55] With isopropenyl chloroformate[58] the mixed anhydride is prepared at room temperature, and during reaction only acetone and carbon dioxide are formed.

**Table 1** Amides *via* Mixed Anhydrides: Use of *C*-acids

| *Reagent* | *Structure* | *Ref.* |
|---|---|---|
| Ethyl chloroformate |  | 57 |
| Isobutyl chloroformate |  | 54, 55 |
| 2-Ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (EEDQ) |  | 59 |
| 2-Isobutoxy-1-isobutoxycarbonyl-1,2-dihydroquinoline (IIDQ) |  | 60, 61 |
| 2-Propenyl chloroformate |  | 58 |

The coupling reagents EEDQ[59] and IIDQ[60,61] permit the formation of amides from carboxylic acids and amines in one pot, at ambient temperatures, without the need for a tertiary base (equation 6).



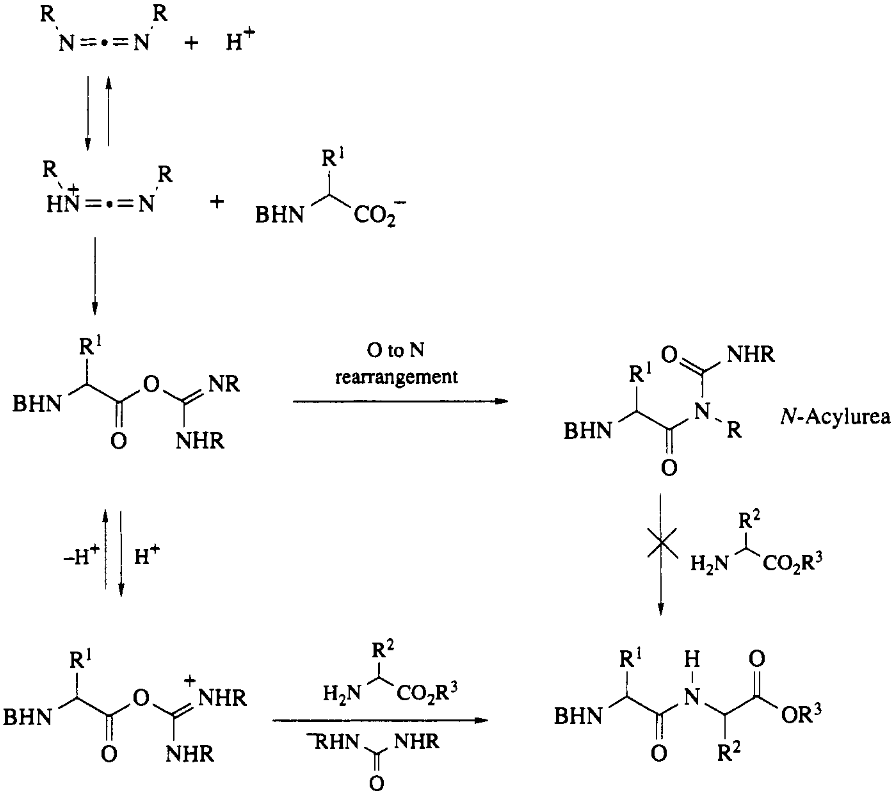
(6)

Carbodiimides are the major coupling reagents in peptide chemistry and are frequently used in solution as well as in solid phase synthesis (Table 2).

**Table 2** Amides *via* Mixed Anhydrides: Use of *C*-acids

| *Reagent* | *Structure* | *Ref.* |
|---|---|---|
| Dicyclohexylcarbodiimide (DCC) |  | 62 |
| Diisopropylcarbodiimide (DIC) |  | 66, 67 |
| 1-Cyclohexyl-3-(2-*N*-methylmorpholiniumylethyl)-carbodiimide-*p*-toluenesulfonate |  | 63 |
| 1-Ethyl-3-(3-dimethylamino)propylcarbodiimide (EDC) |  | 64 |
| Ethylphenylcarbodiimide |  | 68 |
| Ethoxyethyne | ≡—OEt | 75 |
| 4-Dimethylamino-3-butyn-2-one |  | 76 |
| 1-(4-Chlorophenyl)-3-(4-methylpiperazinyl)-2-propyn-1-one |  | 77 |
| Trimethylsilylethoxyethyne | EtO—≡—SiMe$_3$ | 74 |
| 2-Morpholinylethyl isocyanide |  | 73 |
| t-Butyl isocyanide | $Bu^tNC$ | 71, 72 |

The reaction proceeds *via* a 1,2-addition of carboxylic acids to the carbodiimides to give acyllactims (Scheme 3), and leads to the peptide after nucleophilic attack of an amine. The by-product of this reaction, *N,N'*-dicyclohexylurea in DCC-mediated couplings,[62] is easily removed by filtration from the reaction mixture. Because it is not completely insoluble in most organic solvents, contamination of the products occur. The introduction of water soluble carbodiimides[63–65] facilitates the work-up procedure by extracting the urea with water. Diisopropylcarbodiimide[66,67] is frequently used in solid phase synthesis,[46] because its corresponding urea is soluble in a variety of organic solvents and readily removed by filtration.



B = blocking group

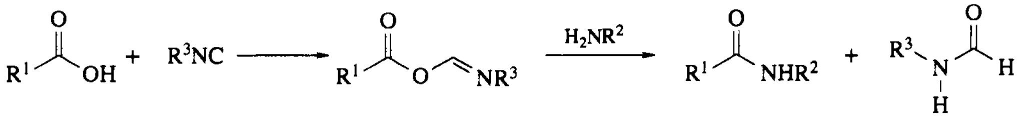
**Scheme 3**

Two side reactions, the O to N acyl shift and racemization, limit the application to some extent. Lower reaction temperatures, shorter reaction times or the use of unsymmetric carbodiimides[68] suppress these reactions. The addition of reactive nucleophiles will be discussed in a later section (active esters).

Dicyclohexylcarbodiimide has been used in the acylation of all common amino acids and is the most familiar condensation reagent in peptide chemistry, in spite of its skin-irritating and allergic properties. Outside peptide chemistry, dicyclohexylcarbodiimide has been used only infrequently for the condensation of carboxylic acids and amines, probably due to its high costs.

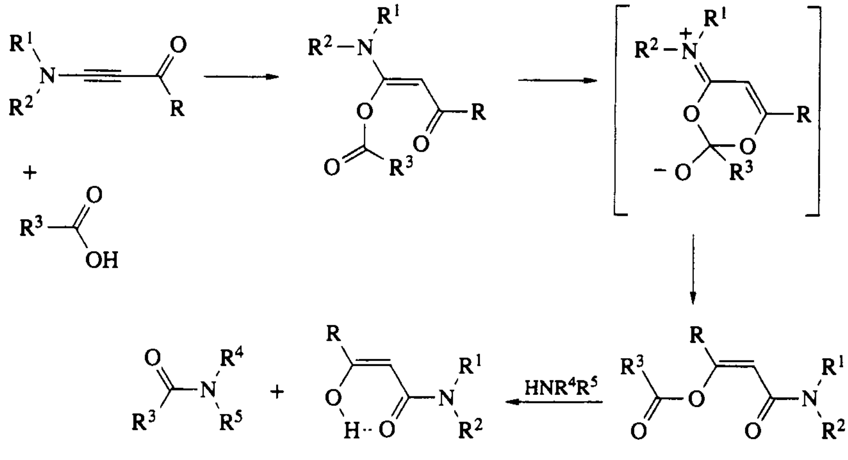
α,β-Unsaturated carboxylic acids[69] and α-oxocarboxylic acids[70] give low yields of amides. The condensation of carboxylic acids with isocyanides is related to that of carbodiimides (equation 7).[71–73] The mild reaction conditions tolerate unprotected hydroxy groups of amino acids even with long reaction times. Generation of side products like acylureas is not possible and racemization is lower than with DCC.

2-Morpholinylethyl isocyanide[73] gives good results in fragment condensations and the by-product is simply removed by acid washing.



(7)

Activation by addition of a carboxylic acid to a triple bond occurs with ethyl ethynyl ether,[74,75] which forms amides *via* reactive enol esters. The reaction is catalyzed by mercury(II) oxide under almost neutral conditions. Push–pull alkynes exert higher reactivity.[76,77] The intermediate enol esters (Scheme 4) rearrange and react with the amino function of a second amino acid. Hydroxy, thiol and imidazole functional groups do not have to be protected. The degree of racemization is low, and yields are good in the case of small peptides.



**Scheme 4**

*(d) Intermolecular mixed from S-acids.*

Activation of aliphatic and aromatic carboxylic acids with sulfuric acid derivatives yields amides (Table 3). Sulfuryl chloride fluoride and primary amines[78] or chlorosulfonyl isocyanate and secondary amines[79] are used as reaction partners.

Activation with sulfonic acid chlorides[80,81] is more general, rendering amides with the possible participation of symmetric anhydrides after disproportionation.[82] This method has also found use in the synthesis of modern β-lactam antibiotics.[83] However, in peptide chemistry this activation method leads to unwanted side reactions, like formation of nitriles in the cases of glutamine and asparagine,[84] and racemization.[85] In a convenient one-pot procedure, the carboxylic acids are activated by sulfonyl chlorides under solid–liquid phase transfer conditions using solid potassium carbonate as base and a lipophilic ammonium salt as catalyst.[86]

**Table 3** Amides *via* Mixed Anhydrides: Use of *S*-acids

| *Reagent* | *Structure* | *Ref.* |
|---|---|---|
| Sulfuryl chloride fluoride | $SO_2ClF$ | 78 |
| Chlorosulfonyl isocyanate | $ClO_2S\text{–}N{=}\bullet{=}O$ | 79 |
| Methanesulfonyl chloride | $MeSO_2Cl$ | 80 |
| Methanesulfonyl chloride | $MeSO_2Cl$<br>(Phase transfer conditions) | 86 |
| 2-Mesitylenesulfonyl chloride |  | 81 |
| *p*-Toluenesulfonyl chloride |  |  |

### *(e) Intermolecular mixed from* P-*acids.*

In recent years organophosphorus reagents have received much attention (Table 4). Their mixed carboxylic–phosphorous acid anhydrides are very reactive intermediates and are opened chemoselectively by nitrogen nucleophiles to give amides. The by-products in these coupling reactions are mostly water soluble, oxygen-containing phosphorus compounds. Therefore, medium scale technical syntheses of amides and peptides are also feasible.[87,88] The tendency for disproportionation to the symmetrical anhydrides is small.[89,90] Most of these reagents activate urethane-blocked amino acids without racemization,[91] while others are rapidly converted to their corresponding azides (DPPA)[92] or active esters[93–96] (BNPP,[97,98] BOP[99,100] and NPTP[101]; *cf.* Section 2.3.1.1.2.iii.a).

Advantages have been claimed for DPPCl[89] and BOP-Cl[102–104] in the condensation of *N*-methylamino acids, namely high yields and low racemization rates. For cyclization to cyclopeptides both DPPA[92,105] and (5-nitropyridyl)diphenylphosphinate,[96] to β-lactams NPTP[101] and DMPC,[106] have been applied.

DPPA, the Bates reagent and BOP are toxic, the latter due to the formation of HMPA. A substitute for the widely used BOP is TBTU [174], which releases tetramethylurea as a harmless side product.

The redox coupling found by Mukaiyama makes use of the facile oxidation of phosphines and the strength of the P—O bond (Table 5). In each case the reaction proceeds *via* an acyloxyphosphonium intermediate (equation 8). The oxidation is carried out by disulfides[108–110] and related compounds,[111,112] DEAD,[113] and halogens.[114–117] Although this method has been applied to the solid phase synthesis of peptides, it has not found broad application.

### *(f) Intermolecular mixed from* N-*acids.*

Carboxylic acid azides give rise to three different reactions under different conditions. Azide coupling (equation 9) was the earliest method[131] in peptide synthesis and is still one of the most important in fragment condensation[132] and preparation of cyclic peptides due to its almost complete lack of racemization. At elevated temperatures a frequent side reaction is the Curtius rearrangement. Trapping of the intermediate isocyanate with amines (equation 10) gives urea derivatives and with carboxylic acids rearranged amides are obtained (equation 11).[133]

Carboxylic acid azides are prepared from carboxylic acid halides or from amino acid/peptide esters *via* hydrazides, followed by nitrosylation with nitrous acid in water[134] or with alkyl nitrites in organic solvents.[135] Also, the aforementioned diphenylphosphorazidate (*cf.* Section 2.3.1.1.2.2.ii.e) is often used in this preparation method starting from carboxylic acids.

Activation of carboxylic acids with carbonyldiimidazole (equation 12) and subsequent reaction with amines gives amides and peptides in good yield.[136–138] Through the same intermediate, the activation also occurs with the more stable *N,N'*-oxalyldiimidazole[139] and the mixture of triphenyl phosphite and imidazole.[140]

Imidazolides are powerful acylating agents. Therefore moisture has to be excluded and the acids have to be preactivated before addition of the amine. The tendency toward racemization is low, especially in DMF. The by-products of the reaction, imidazole and carbon dioxide, are easily removable. Other activating reagents (Table 6) can be applied. The advantage of COMODD[141] and *N,N'*-carbonyldi-2-thione-1,3-thiazolidine[142] is that the activated carboxylic acids are stable and isolable.

### *(iii) Carboxylic acid esters*

The direct aminolysis of unactivated esters and lactones is particularly difficult with secondary amines, since even primary amines require temperatures higher than 200 °C.[143] Application of high pressure (8 kbar, 1 bar = 100 kPa) at lower temperatures (room temperature to 45 °C) makes this reaction possible.[144] Sodium cyanide catalyzes this reaction at atmospheric pressure and it proceeds without racemization of amino acid esters.[145]

Alternative methods include deprotonation of the amine, to enhance its nucleophilicity, by one equivalent of sodium methoxide,[146] sodium amide, metallic sodium,[147] *n*-butyllithium,[148] sodium hydride in dimethyl sulfoxide[149] or Grignard reagent.[150] Under less drastic basic conditions 2-hydroxypyridine catalyzes the reaction at elevated temperatures (130–170 °C).[151]

Treatment of the parent ester with Lewis acids like boron tribromide and subsequent addition of amine results in amides in good yields.[152]

**Table 4** Amides *via* Mixed Anhydrides: Use of *P*-acids

A mild and general method involves pretreatment of amines with one equivalent of trimethylaluminum followed by addition of the ester or lactone.[153] Similarly $RhCl_3$ catalyzes amide bond formation leading to diketopiperazines.[154]

Some simple examples exploit the electrochemical amidation of esters with amines in the cathodic compartment.[155]

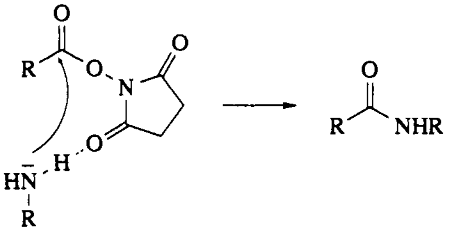
*(a) Intermolecular from active esters.*

To facilitate the amidation of esters, phenols substituted with strongly electron-withdrawing groups have been applied to this reaction. The nucleophile, a primary or secondary amine, only attacks the ester bond at the electrophilic carbonyl group. This reaction has found broad acceptance in peptide chemistry, also due to the fact that many active esters are available as crystalline compounds. Table 7 shows the most important groups. Aromatic alcohols like *p*-nitrophenols[156] or pentafluorophenols[157] are often used to prepare active esters, the latter compounds being used in combination with the *N*-amino protecting group FMOC in solid phase synthesis. These aminolyses can further be catalyzed by the addition of hydroxybenzotriazole.[158]

*O*-Acyl derivatives of substituted hydroxylamines react readily with amines and amino acids with almost no racemization due to an anchimeric assistance (equation 13) in the transition state. The active esters are prepared either by the activation reagents shown in Table 7 or by activation with DCC and trapping by the hydroxylamine. TBTU[174] reacts fast and has found increasing interest in solid phase synthesis. Following a similar mechanism, oxime esters[159,160] are also used for activation.



(13)

*C*-Terminal amino acid oxime esters on a polymeric phase have been applied to solid phase peptide synthesis;[161] the protected peptide is cleaved by amino acid esters and other nucleophiles.

Enol ester intermediates are formed from cyclic carbonates,[162,163] a color change indicating the progress of the reaction.

### *(b) Intermolecular from active thioesters.*

In analogy to the active esters, thioesters are prepared by condensation of thiols with carboxylic acids/DCC[178] or carboxylic acid chlorides.[179–181] Aryl thioesters react readily with nucleophiles like amines to give amides. Peptides are prepared without racemization. In the case of *t*-butyl thioesters activation is accomplished by treatment with $AgO_2CCF_3$.

2,2′-Pyridine disulfide reacts with triphenylphosphine and carboxylic acids to yield active thioesters, which can be amidated with secondary amines.

Due to their obnoxious smell and catalyst-poisoning properties, active thioesters have only encountered limited use.

### *(c) Miscellaneous.*

Lewis acids like tetrachlorosilane in pyridine[182,183] or titanium tetrachloride[184] are reported to give simple amides in moderate yields. Boron trifluoride etherate in the presence of a strong base amidates carboxylic acids in an excess of primary amine.[185] These reactions have not found broad application.

### *(d) Enzyme-catalyzed peptide bond formation.*

The fact that hundreds of coupling reagents have been developed for peptide chemistry demonstrates that there is still a need for general methods with high reaction rates employing equimolar amounts of carboxy and amino components without racemization.[186,187]

Hydrolyzing enzymes, especially proteases, constitute an alternative to chemical synthesis. The principal advantages are the use of unprotected side chain amino acids (except cysteine), racemization-free couplings (especially in fragment couplings) and the specificity of the involved enzyme. As a consequence, the number of synthetic steps is drastically reduced and the procedures are environmentally safe.

The peptide-forming reaction can be carried out under thermodynamic or kinetic control (equation 14). The equilibrium between substrates and product is unfavorable for the peptide (endergonic process due to a loss in entropy). Shifting the equilibrium to the right (increasing $K_{syn}$) is achieved by optimizing the reaction conditions through increasing $K_{ion}$ by proper choice of pH, use of water miscible organic solvents and use of biphasic systems. The reversal of hydrolysis by formation of insoluble products or extraction of products increases the yield.

For these thermodynamically controlled syntheses a variety of enzymes may be used, *e.g.* serine proteases like chymotrypsin[188] and trypsin,[189] cysteine proteases (thiol proteases) like papain,[190,191] aspartate proteases like pepsin[192] and metalloproteases like thermolysin.[193]

Kinetically controlled syntheses, which are more often studied, can only be carried out by enzymes forming a reactive acyl–enzyme intermediate (serine or cysteine protease, Scheme 5). The reaction starts with weakly activated amino acids (*e.g.* esters), and the rapidly formed reactive intermediate RCOE is attacked by nucleophiles like amines and water. If $k_4 \gg k_3$ and $k_4[H_2NR'] > k_3[H_2O]$, the desired peptide accumulates. Short reaction times, low enzyme concentrations and the danger of secondary hydrolysis of the peptide product are characteristics of these reactions. The optimal pH usually lies above pH 8.

Immobilized enzymes which have the same efficiency as soluble enzymes can easily be recovered and reused and exert no proteolytic activities on synthesized peptides.[194]

(15)

In the case of thermolysin, a thermodynamically controlled reaction takes place. Only L-Phe reacts with the side chain unprotected L-Asp. The reaction proceeds to the product side by the formation of an insoluble salt with the remaining D-Phe.

Enkephalins, hormones with morphine-like activities, have been synthesized with chymotrypsin and papain[196] as well as carboxypeptidase Y[197] under kinetically controlled conditions.[190]

Further commercial interest was found by the transpeptidation reaction of porcine insulin to human insulin, the latter only differing in the last amino acid of the B-chain (Ala-B30 to Thr-B30). This reaction proceeds under kinetic control with trypsin,[198,199] carboxypeptidase Y[200] or *achromobacter lyticus* protease I.[201]

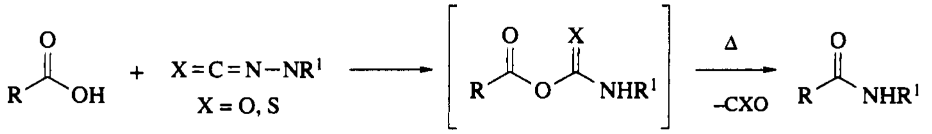
The enzymatic method was extended using chemically modified serine proteases like thiolsubtilisin[202] for the synthesis of the ribonuclease $T_1$ (12–23) fragment.

Recent progress was made in the incorporation of D-amino acids in peptides *via* subtilisin-mediated syntheses in organic solvents[203] or in the application of the nonproteolytic lipases[204] in anhydrous organic solvents.

In general, the enzymatic methods cannot be used universally and have to be optimized for each peptide synthesis. High specificity of an enzyme drastically reduces its wide application; broad specificity has the advantage of universal use, but suffers from early proteolytic cleavage of products.

### *2.3.1.1.3 Activation of the amino group*

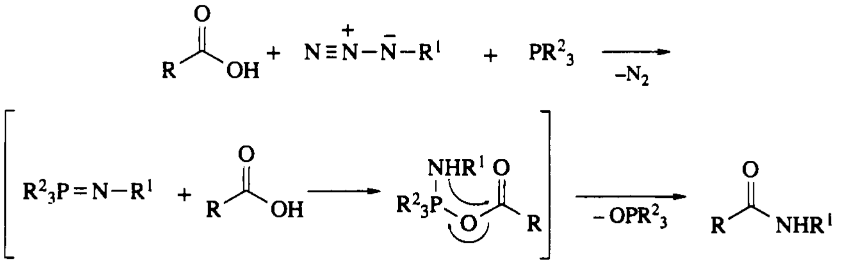
A conceptual alternative way to the activation of the carboxylic acid function is the reaction of carboxylic acids with amino groups activated as isocyanates[205,206] and isothiocyanates (equation 16).[207] Preparation of these derivatives is racemization free. The reaction proceeds *via* mixed acid anhydrides in aromatic hydrocarbon solvents at elevated temperatures, and decarboxylation leads to the *N*-substituted amide. Pyridine as solvent enhances the conversion rate but increases also the amount of the urea side product *via* disproportionation.[205] Application to peptide chemistry is limited, because peptide ester fragments tend to form hydantoins.[205]



(16)

Reaction with *N*-urea-protected amino acids is racemization free, whereas the fragment condensation shows considerable racemization.[208] The analogous condensation with isothiocyanates[207] runs at higher temperatures.

Activation of organic azides with trivalent phosphines under mild conditions followed by reaction with carboxylic acids leads to amides *via* iminophosphoranes in moderate to good yields (equation 17).[209] The driving force of this method lies in the intramolecularity of the acyl transfer and the expulsion of a thermodynamically stable end product.



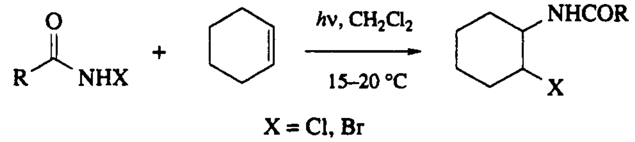
(17)

## 2.3.1.2 Alkylation and Arylation of Amides

The preparation of *N*,*N*-disubstituted amides is easily performed with sodium salts of *N*-monosubstituted amides and alkyl bromides or iodides.[210]

Under phase transfer conditions (boiling benzene, 50% aquous sodium hydroxide solution and tetra-*n*-butylammonium hydrogenphosphate) benzamides are monoalkylated.[211] In the solid–liquid PTC system potassium hydride, tetrahydrofuran and 18-crown-6, acidic trifluoroacetamides are rapidly deprotonated and alkylated with lower alkyl, allyl and benzyl halogenides in high yield.[212] Methylation of trifluoroacetamides is carried out under less basic conditions in KOH/acetone.[213] A similar reaction in KOH/DMSO generally allows the efficient reaction of benzamide and acetanilide with primary alkyl halides; with secondary halides only moderate yields are accomplished, whereas tertiary halogenides are not alkylated due to dehydrohalogenation.[214]

The photochemical 1,2-addition of *N*-halogen amides to alkenes results in a mixture of diastereomers (equation 18).[215]

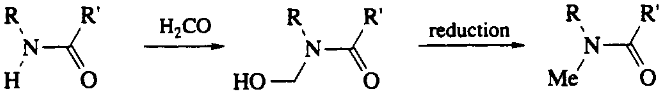


(18)

*N*-Arylation of benzamide or acetamide is possible under drastic reaction conditions in aryl halides as solvent and at high temperatures,[216] with copper powder as catalyst. A simplified procedure, using tris(3,6-dioxaheptyl)amine (TDA-1) and copper(I) chloride as PTC system, performs this reaction with quasi-stoichiometric quantities of bromobenzene under relatively mild conditions.[217]

The addition of mercury(II) nitrate activated alkenes to amides follows the rule of Markovnikov. Subsequent $NaBH_4$ demercuriation leads to more highly substituted amides in moderate to good yields.[218]

An efficient two-step procedure for the *N*-methylation of amides (equation 19) involves the preparation of intermediate methylols with subsequent reduction using triethylsilane, hydrogen/Pd–C[219] or cyanoborohydride.[220,221]

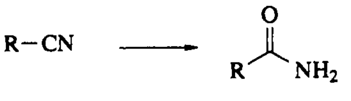


(19)

### 2.3.1.3 Nitriles

### *2.3.1.3.1 Hydration*

Under neutral conditions and at high temperatures (*ca.* 180 °C) nitriles react with water to give amides (equation 20). ZnO and CdO are efficient catalysts.[222] To accelerate the reaction rate, acid treatment under a variety of conditions can be carried out: hydrochloric acid,[223] hydrogen chloride or bromide in formic acid,[224] alcoholic hydrogen chloride solutions,[225–227] polyphosphoric acid[228,229] and boron trifluoride in aqueous acetic acid[228] are all effective.



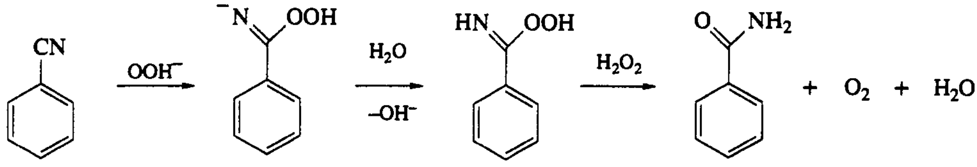
(20)

Alternatively, applying basic reaction conditions, partial hydrolysis with hydroxide-loaded anion exchangers in boiling water leads to aromatic amides in good yield.[230–232]

Hydrolysis with powdered potassium hydroxide or potassium fluoride on alumina[233] in *t*-butyl alcohol converts nitriles to amides without further hydrolysis to carboxlic acids.[234] Under similar conditions, addition of alkyl halides gives *N*-alkylcarboxyamides.[235] Less drastic acidic or basic hydrolysis conditions involve disproportionation of alkaline hydrogen peroxide with concomitant hydration of the nitrile (equation 21).[236,237]

Aromatic nitriles generally afford amides in yields of 80–90%, but in the aliphatic series only 50–60% yields are achieved.

A modification of this method using phase transfer catalysis leads to improved yields in shorter reaction times.[238]



(21)

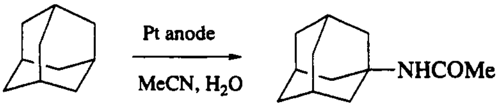
With the help of metal catalysis amidation takes place at room temperature under apparently neutral conditions. Manganese dioxide in large quantities,[239] or, even better, manganese dioxide on silica gel,[240] is well suited to this conversion. Even compounds with functional groups labile to manganese dioxide, for example benzylic groups, are suited for the hydration. With pentacarbonylmanganese bromide, nitrile hydration takes place under PTC conditions.[241]

Copper(0) catalyzes the hydration of sensitive nitriles like 2-acrylamide.[242]

Other processes involving metal catalysts like nickel(II), zinc(II), palladium(II) and ruthenium(I) have not found broad application, but a related amidation of nitriles uses the ruthenium catalyst $[RuH_2(PPh_3)_4]$.[243]

### *2.3.1.3.2 Ritter-type reactions*

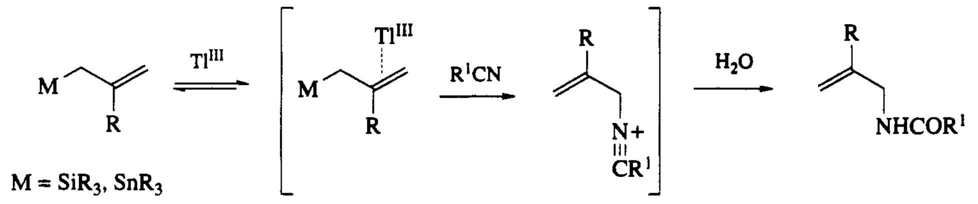
In general, treatment of carbonium ions with nitriles under a variety of conditions yields *N*-substituted amines.[244] Anodic oxidation in acetonitrile converts selected aliphatic compounds to acetamides, *e.g.* adamantane to adamantylacetamide (equation 22).[245]



(22)

Alkenes and alcohols condense with nitriles under drastic acidic conditions. In most cases sulfuric acid is used either neat or with solvents such as acetic acid.[244,246] In liquid hydrogen fluoride containing defined amounts of water, nitriles react with linear or branched alkenes to form amides in good yields.[247]

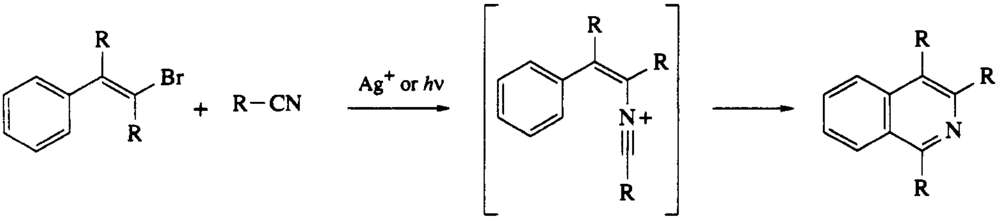
Treatment of allylsilanes and allylstannanes with thallium(III) salts in acetonitrile activates the alkene for nucleophilic attack of the nitrile group. The generated nitrilium cation (equation 23) is hydrolyzed to the corresponding *N*-allylamide.[248]



(23)

Allyl halides react with acetonitriles after anodic oxidation[245,249] under acidic conditions[244,250] or in the presence of nitrosonium hexafluorophosphate[251] to give the corresponding amides.

Vinyl cations, generated from β-arylvinyl bromides by silver(I)-assisted solvolysis or by photolysis, are trapped by nitriles to yield isoquinolines (equation 24).[252]

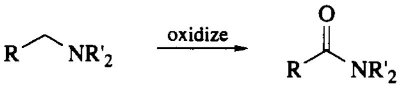


(24)

The reaction of nitriles with carbon monoxide, carbonyl compounds, carboxylates, ketenes, 1-aminoalkynes and carbenes has been reviewed recently.[250]

### 2.3.1.4 Oxidation

Oxidation of amines containing α-hydrogen atoms is of variable difficulty (equation 25). Permanganate oxidation of 1-aryl-5-(tertiary)amino-*v*-triazoles leads to the corresponding amides.[253] Benzyl(triethyl)ammonium permanganate[254] oxidizes a variety of simple, substituted amines. Tertiary amines give good yields of amides, but secondary and primary amines give moderate yields due to the formation of imines.



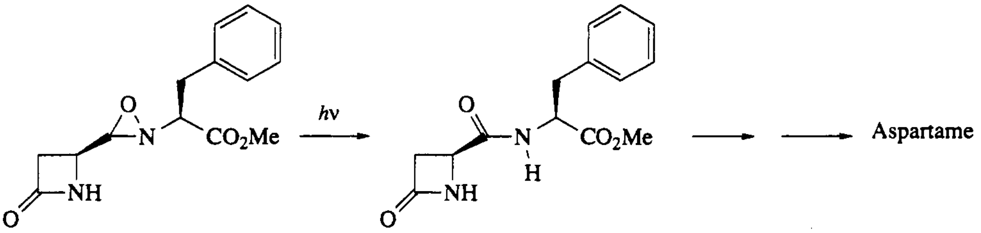
(25)

A similar selective oxidation of *N*-methyl groups has been accomplished with osmium tetroxide in the alkaloids delphinine and mesaconitine.[255]

Lactams are formed by bromination (bromine, *N*-bromosuccinimide) of cyclic tertiary amines, resulting in an intermediate iminium salt that can be isolated.[256] Oxidation by metal oxides,[257] autoxidation,[258] photochemical oxidation[259] and electrooxidation[260] are alternatives with limited scope.

The oxidation of aldehydes in the presence of amines occurs at low temperatures with nickel peroxide.[261] Similarly, the oxidation of aromatic aldehydes with manganese dioxide[262] or ruthenium chloride[263] in the presence of sodium cyanide and an amine leads to the corresponding amides.

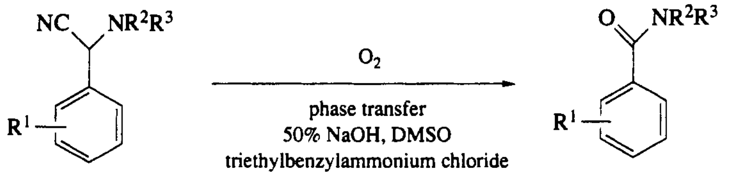
The dipeptide sweetener aspartame has been synthesized *via* an oxaziridine, which was rearranged by irradiation with UV light (equation 26).[264]



(26)

Aldehyde bisulfite adducts are oxidized by dimethyl sulfoxide/acetic anhydride and converted to simple amides in good yield.[265]

In the oxidative decyanation of dialkylaminophenylacetonitriles under phase transfer conditions the generated α-carbanion is oxidized by a stream of oxygen (equation 27).[266] Catalytically, a direct conversion occurs with the system consisting of $Pd(OAc)_2$, benzyl bromide and potassium carbonate.[267]

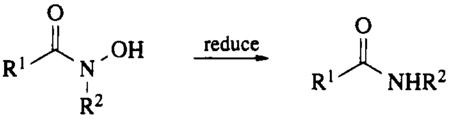


(27)

Oxidations of hydroxamic acids[268] by periodate (assumed to involve a nitrosylacyl intermediate) and of hydrazides[269] by potassium ferrocyanide, followed by quenching with amines, are of limited preparative value.

### 2.3.1.5 Reduction

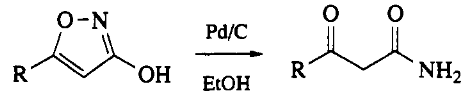
Under mild conditions, titanium trichloride reduces hydroxamic acids to the corresponding amides and lactams (including β-lactams) in good yield (equation 28).[270]



(28)

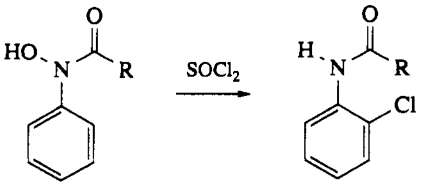
Brief heating of hydroxamic acids in phosphorus tribromide/benzene,[271] as well as treatment with Raney-Ni,[272] results in the formation of lactams.

Isoxazole derivatives, considered as cyclic β-ketohydroxamic acids, are opened by hydrogenation over palladium or platinum[273] to give the corresponding β-ketoamides in excellent yields (equation 29).



(29)

Thionyl chloride reacts with *N*-arylhydroxamic acids to form the corresponding amides *via* ortho-halogenation (equation 30).[274]



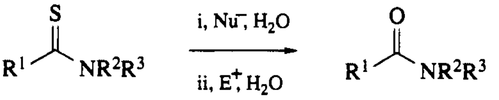
(30)

Hydrazides are hydrogenated by a substantial excess of Raney nickel.[275] Phenylhydrazides are reductively cleaved over palladium/charcoal as catalyst, and the corresponding amides are obtained in good yields.[276]

The reductive cleavage of benzoyl azide runs at low temperature with tetracarbonylhydridoferrate, $[HFe(CO)_4]^-$,[277] and with diphosphorus tetraiodide in benzene under reflux.[278] Curtius rearrangement side products are not observed.

### 2.3.1.6 Thioamides

Due to the ease of preparation of thioamides (*cf.* Chapter 2.4. of this volume) there is considerable interest in the desulfurization of these to the corresponding amides (equation 31).

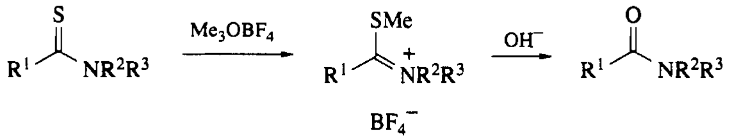


(31)

With the exception of a few examples of nucleophilic attack on the thiocarbonyl group, including a more recently published method using sodium hydroxide under phase transfer conditions,[279,280] most conversions are carried out with oxidative reagents. Sodium peroxide,[281] dimethyl sulfoxide with acid[282] or iodine,[283] selenium-derived reagents[284,285] and bis(*p*-methoxyphenyl)telluroxide[286] have been used.

Catalytic amounts of halogen accelerate the conversion, especially with strong base under phase transfer conditions.[280,287] *m*-Chloroperbenzoic acid reacts with thiolactams and thioamides and gives good yields of amides with precipitation of sulfur.[288]

Alkylation of thioamides with Meerwein's reagent (trialkoxonium fluoroborate)[289] proceeds *via* a thioiminoester and subsequent base hydrolysis with sodium carbonate (equation 32). For the synthesis of 2-pyridones from 2-thiopyridones, chloroacetic acid has been used.[290] Mild reaction conditions are provided by nitrosyl species which are derived from a variety of reagents: excess $NaNO_2/HCl$[291] in aqueous medium, nitrosonium tetrafluoroborate[292] in dichloromethane, dinitrogen tetroxide[293] in acetonitrile at low temperature and *t*-butyl thionitrate.[294]

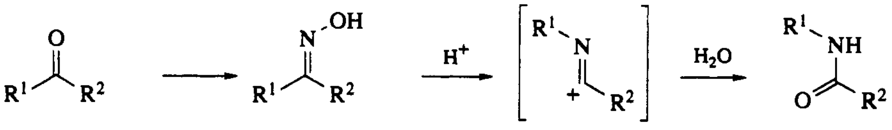


(32)

### 2.3.1.7 Rearrangements

#### *2.3.1.7.1 Beckmann, Schmidt*

The Beckmann rearrangement converts oximes to amides or lactams and was reviewed recently (equation 33).[295]



(33)

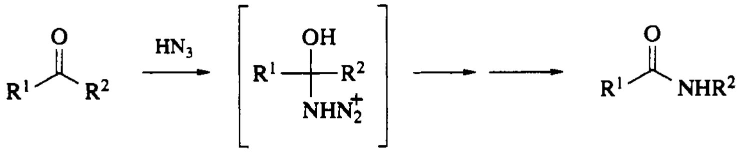
In general, this rearrangement is stereospecific, involving the migration of the residue *anti* to the leaving group on nitrogen. The reaction usually occurs under acidic conditions. $PCl_5$ in ether,[296] thionyl chloride in dioxane,[297] boric acid[298] and more frequently polyphosporic acid[299] are used at elevated temperatures. Due to its viscosity and low dissolving ability resulting in large reaction volumes, polyphosphoric acid can be effectively replaced by trimethylsilylpolyphosphate[300] (readily prepared from phosphorus pentoxide and hexamethyldisiloxane) or the two phase system polyphosphoric acid/xylene.[301] The mildly basic hexamethylphosphoramide causes rearrangement at higher temperatures.

Activation of the oxime with benzenesulfonyl chloride or *p*-toluenesulfonyl chloride leads to sulfonate esters which undergo the Beckmann reaction with or without isolation.[302,303] The sulfonate esters also rearrange under mild reaction conditions on silica gel.[304] Under neutral conditions, *N,N*-carbonyldiimidazole activates oximes in the presence of allyl bromide, followed by spontaneous Beckmann rearrangement.[305]

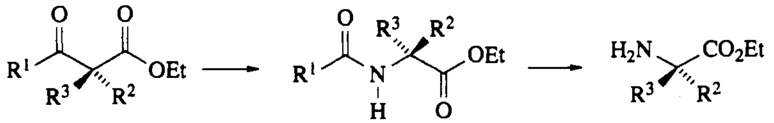
Dependent on the stereochemistry of the oxime sulfonate and the different groups $R^1$, $R^2$, in many cases only one preferred stereoisomer rearranges. In hydrochloric acid/acetic acid, isomerization gives rise to only one final product.[306]

Hydroxylamine sulfonic acid,[307] hydroxylamine and catalytic amounts of trifluoromethanesulfonic acid,[308] or *O*-mesitylenesulfonylhydroxylamine[309] converts ketones directly to the lactams under mild conditions (reflux in formic acid).

The Schmidt reaction is closely related to the Beckmann reaction (equation 34). Acyclic and cyclic ketones are transformed to amides and lactams by treatment with hydrogen azide.[310,311] With bridged bicyclic ketones, the regioselectivity of the migration is opposite to the direction of the Beckmann reaction.[311,312] The Schmidt reaction has been applied to asymmetric synthesis starting from optically active α,α-dialkylated β-keto esters. High chemical and optical yields have been obtained (equation 35).[313]



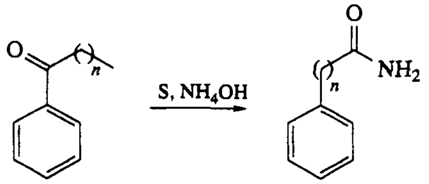
(34)



(35)

#### *2.3.1.7.2 Willgerodt*

In the Willgerodt reaction, aryl alkyl ketones react with sulfur and ammonium hydroxide to give amides with the same number of carbon atoms (equation 36).[314] In an extension, aliphatic ketones,[315] aldehydes[316] and unsaturated hydrocarbons[317] also can be used as starting materials.



O
n
S, NH4OH
O
n
NH2

(36)

The Kindler modification of the Willgerodt reaction uses sulfur and dry amines, ammonia, primary amines or secondary amines, which leads to the formation of thioamides (conversion of thioamides to amides *cf.* Section 2.3.1.7).[318] This reaction can also be extended to aldehydes,[319] hydrocarbons[320] and heterocyclic ketones.[321] Due to the usually low to moderate yields this reaction has not found general application.

### *2.3.1.7.3 Ugi four component reaction*

The four component condensation (Ugi reaction)[322-324] converts a mixture of substituted amine, isonitrile, aldehyde (or ketone) and carboxylic acid (Scheme 6) to α-acylaminocarboxylic acid amides (pathway a), to diacylamines (pathway b) and to α-aminocarboxylic acid amides (pathway c).[325]

**Scheme 6**

Also, β-lactams are obtained in high yield by the reaction of β-aminocarboxylic acids with aldehydes and isocyanides.[324,326]

Tripeptides can be obtained in good yields by reacting primary amines with aldehydes leading to the intermediate Schiff base. Applying pathway (b; Scheme 6) with isocyanide amino acid esters and *N*-protected amino acids, the Ugi reaction occurs[322,323] with good yields (equation 37). Asymmetric induction on the new stereogenic centre (*) is low, but can be enhanced by the use of chiral amines.

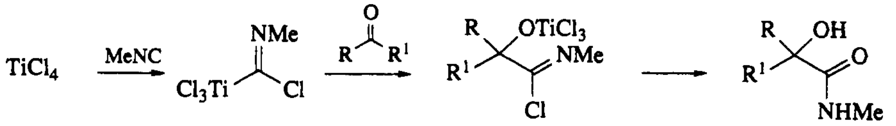
(37)

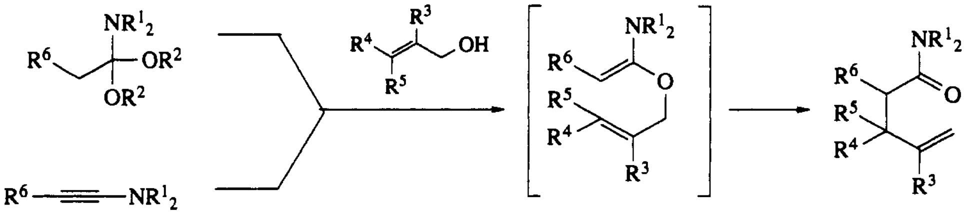
A stereochemical control of the Ugi reaction can be effected with carbohydrates as chiral templates (*e.g.* tetrakis(*O*-pivaloyl)galactosylamine), which gives rise to easily separable amides. From these a variety of non-natural amino acids can be derived after acidic hydrolysis.[327] The Passerini reaction,[328] related to the Ugi rearrangement, gives α-hydroxyamides. A modification of this reaction using titanium tetrachloride gives α-branched amides in high yields *via* *C*-metalated imidoyl chlorides[329] (equation 38).



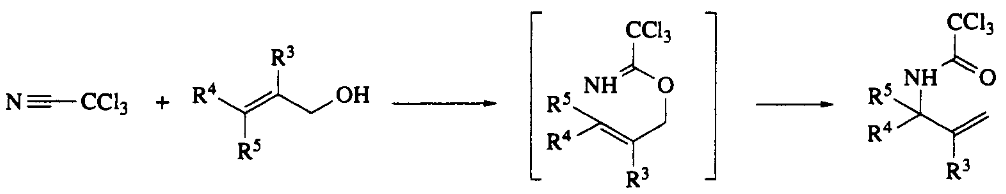
(38)

### 2.3.1.7.4 Miscellaneous

The amide acetal Claisen rearrangement[330] and the ynamine Claisen rearrangement[331,332] proceed *via* a common [3,3] sigmatropic shift of *N,O*-ketene acetals (equation 39) and lead to $\gamma,\delta$-unsaturated amides under mild conditions. Modification of this procedure involves the use of 3-(trimethylsilyl)allyl alcohols for the preparation of $\beta,\gamma$-unsaturated amides,[333] or conversion of propargyl alcohols to $\beta$-allenic amides, which may be rearranged to 2,4-dienamides.[334] Similarly, allylic and propargylic imidic esters[335] undergo stereospecific [3,3] sigmatropic rearrangement to allylic acetamides.



(39)

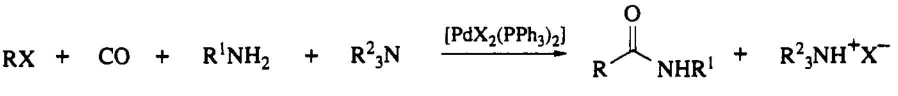


(40)

With trichloroacetimidates, 1,3-conversion of allylic alcohols to allylic amines proceeds smoothly (equation 40).

### 2.3.1.8 Construction of the Carbon Frame

In the Heck reaction, aryl, heterocyclic and vinyl halides[336,337] or aryl triflates[338] react with excess carbon monoxide and primary or secondary amines to give substituted amides, in the presence of a palladium(II) catalyst (equation 41). *Cis*- and *trans*-vinyl halides react stereoselectively.

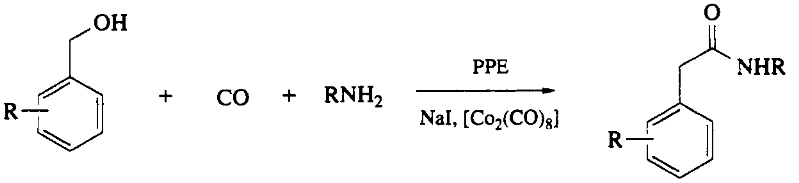


$$RX + CO + R^1NH_2 + R^2{}_3N \xrightarrow{[PdX_2(PPh_3)_2]} RC(O)NHR^1 + R^2{}_3NH^+X^- \quad (41)$$

Intramolecularly, insertion of carbon monoxide into vinyl halides bearing a secondary amino group yields $\alpha$-methylene five-, six- and seven-membered ring lactams.[339]

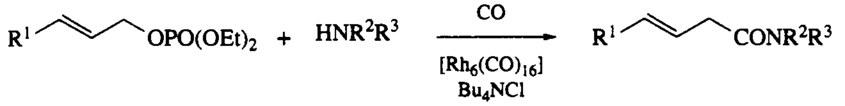
Catalytic double carbonylation of organohalogen compounds[340,341] or simple alkenes[342] needs higher CO pressures (10 atm at room temperature), and mainly provides $\alpha$-ketoamides.

Substituted benzyl alcohols can be converted with cobalt carbonyl to the homologous amides under mild conditions, even using sterically hindered secondary amines (equation 42).



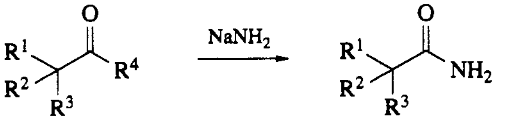
(42)

Vinyl bromides are directly aminocarbonylated by nickel carbonyl and amines.[343] Very similarly, $Rh_6(CO)_{16}$ and $Bu_4NCl$ as catalyst convert allylphosphates to β,γ-unsaturated amides *via* π-allylrhodium complexes (equation 43).[344] Although palladium(0) complexes are more reactive than rhodium(I) complexes, palladium(0) complexes undergo side reactions, like reductive elimination in the presence of carbon monoxide, and direct nucleophilic attack by amines.



(43)

The Haller–Bauer reaction is applied to nonenolizable ketones which react with fresh sodium amide to form amides (equation 44).[345] Cleavage of aliphatic or alicyclic phenyl ketones to produce tertiary carboxamides is the most useful. With equivalent amounts of 1,4-diazabicyclo[2.2.2]octane (DABCO) the reaction proceeds under milder conditions.[346]



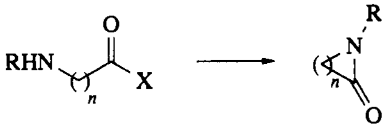
(44)

## 2.3.2 LACTAMS

### 2.3.2.1 Intramolecular Acylation of Amino Acid Derivatives

Generally, the formation of lactams follows the same activation procedures as those discussed in Section 2.3.1.1.

To minimize dimerization products, intramolecular condensations have to be carried out under carefully controlled conditions and in high dilution. The formation of small rings obeys the Baldwin rules (equation 45).[347]



(45)

$n \geq 2$; X = OR, OH

Simple five-, six- and seven-membered lactams are obtained under cyclodehydration conditions by boiling ω-amino acids and alumina or silica gel in excess toluene.[348]

Metal compounds like organostannyl oxides[349] and titanium(IV) alkoxides[350] have been used in the synthesis of macrocyclic lactams.

Reduced copper–titanium catalysts convert ε-aminocapronitrile to ε-caprolactam.[351]

Intramolecular opening of *N*-(haloalkyl)azetidin-2-ones *via trans* amidation affords medium and unstrained ring azalactams.[352]

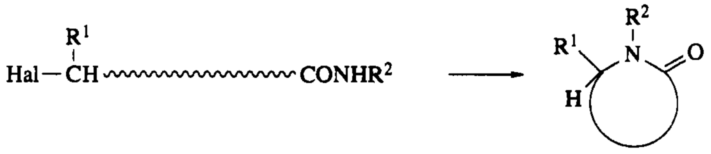
For the preparation of cyclic peptides, standard procedures are still the azide and the active ester method. In a variety of bicyclic analogs of somatostatin, azide coupling is applied twice and yields can be improved by catalysis with *N*-hydroxybenzotriazole.[353]

Cyclopeptide alkaloids are prepared in good yield by catalytic hydrogenation of pentafluorophenyl esters of ω-(*Z*)-aminocarbocyxlic acids. The slow release of the amino function under these conditions minimizes dimerization.[354]

Other masked forms of the ω-amino function include the azido function, which can be readily reduced by triphenylphosphine[355] and the nitro function, which can be reduced by standard hydrogenating procedures including an electrochemical process.[356]

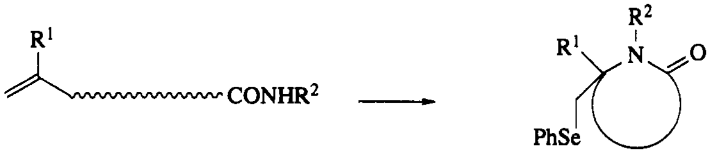
### 2.3.2.2 Intramolecular Alkylation of Amide Derivatives

Cyclization of ω-halocarboxamides (equation 46) requires the use of metallic amides and hydrides under anhydrous conditions. Phase transfer catalysis with strongly basic ion exchange resins in 50% sodium hydroxide solution give four- to seven-membered lactams in good to excellent yield.[357]



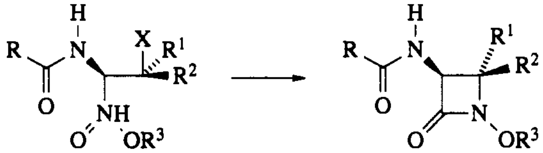
(46)

Reaction of *N*-alkylalkenamides with organoselenium compounds activates the double bond and gives rise to lactams (equation 47).[358]



(47)

In total syntheses of β-lactam antibiotics, the formation of 2-azetidinones is crucial. In a biomimetic synthesis, the N—C4 bond is best closed by the open chain hydroxamate (equation 48),[359] because, depending on the different p$K_a$ values of the three potentially ionizable positions, only the ring-forming amide is ionized. β-halohydroxamates are cyclized by base treatment, whereas β-hydroxyhydroxamates cyclize *via* the Mitsunobu reaction (diethyl azodicarboxylate, $Ph_3P$).[360] More highly substituted precursors yield isomeric β-lactams after rearrangement.[361]

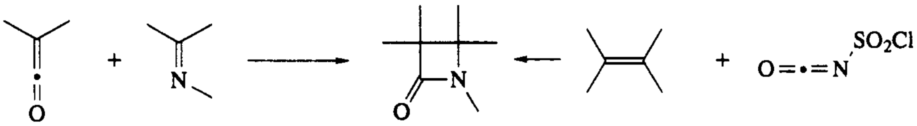


(48)

Under oxidative (iodosobenzene diacetate, $I_2$) and photolytic conditions some nonactivated amides from the alkaloid and steroid series form lactams *via* radical mechanisms.[362]

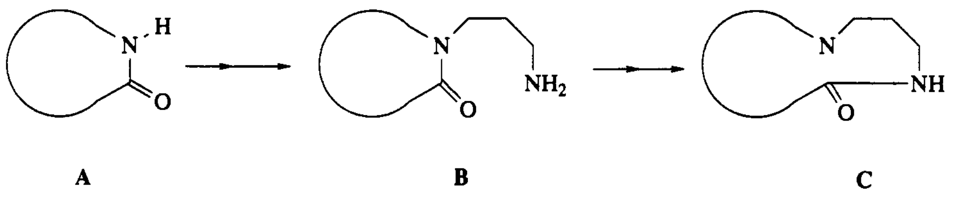
### 2.3.2.3 Construction of the Carbon Frame

The main principles of lactam, especially β-lactam, formation by cycloaddition, exemplified by equation (49),[363] are described in Volume 5, Part 2 of this series.



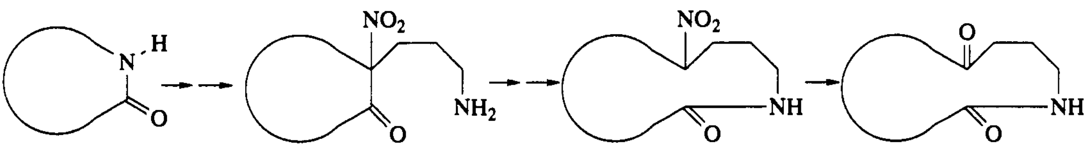
(49)

Chain elongation leading to ring enlargement of lactams takes place in the ZIP reaction (equation 50),[364] where derivatives of trimethylenediamines isomerize to lactams containing a secondary amine and a monosubstituted amide. The reaction sequence can be repeated several times to gain access to larger ring systems.



(50)

In a modified reaction sequence starting with cyclic α-nitro ketones the same reaction leads to nitrolactams, which can be converted to ketolactams in moderate yields (equation 51).[365] The same class of compounds is obtained when α-alkylamino-β-diketo derivatives are treated with base.[366]

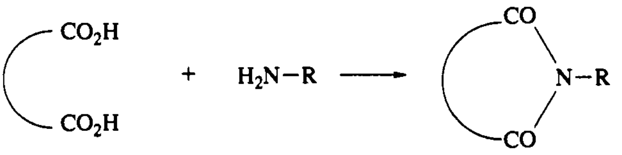


(51)

## 2.3.3 IMIDES

Imides are monoacyl derivatives of amides or lactams and are used as valuable intermediates in organic synthesis as well as in biologically active compounds like drugs, fungicides and herbicides.

The preparation of imides was reviewed recently and many methods are recommended.[3–6,367] Under somewhat drastic conditions (≈ 200 °C) dicarboxylic acids react with ammonia, or compounds which are able to produce ammonia like urea, thiourea, formamide, sulfamic acid, ammonium carbonate and others to form cyclic imides (equation 52).[367] Monoammonium salts of dicarboxylic acids give imides under pyrolytic conditions when distilled under reduced pressure.[368]



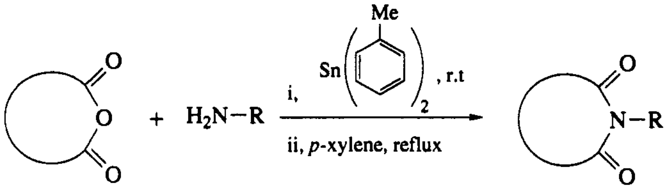
(52)

Ammonia and amines react with partially or fully activated carboxylic acid derivatives (acylating reagents) like acid anhydrides, acid halides, ammonium salts of monoesters, monoamides with heating, diesters under basic conditions and dinitriles after partial hydrolysis.[367]

Intramolecular cyclization occurs with carboxylic acid nitriles, amide nitriles, and ester amides under strongly basic and anhydrous conditions.

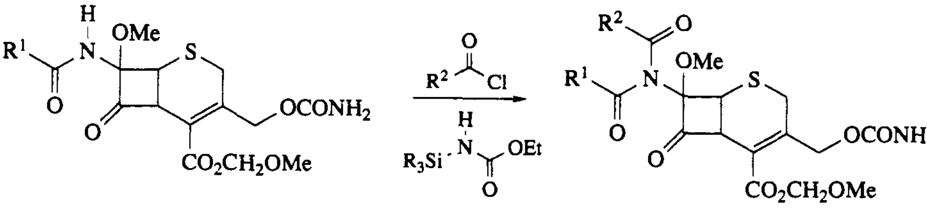
To avoid gaseous ammonia dicarboxylic anhydrides are heated with a slight excess of urea, until the cessation of gas evolution indicates completion of the reaction.[368]

Under milder, neutral conditions, organometallics like 1,1-dimethylstannocene (equation 53) react as Lewis acid and dehydrating reagents at room temperature with cyclic anhydrides and amines.[369]



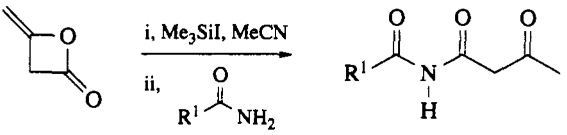
(53)

Acylation of amide bonds in peptides can be accomplished by silylation with trimethylsilyl chloride followed by treatment with acid chlorides.[370] A modified procedure has been applied to acylation of the sensitive β-lactam antibiotic cephamycin, where silylamides like trimethylsilylurethane trap generated HCl (equation 54).[371]



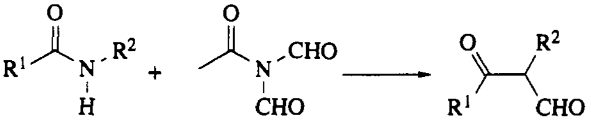
(54)

Diketenes react with carboxamides in the presence of trimethylsilyl iodide to yield *N*-acetoacetylcarboxamides (equation 55).[372]

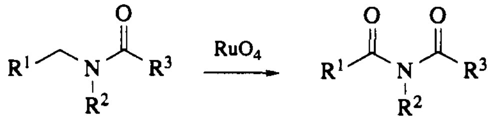


(55)

With the powerful formylation reagent *N*,*N*-diformylacetamide imides are obtained from amides or lactams in good yield (equation 56).[373] Oxidation reactions also have found some application in the synthesis of imides. For example, catalytic amounts of ruthenium tetroxide and 10% aqueous $NaIO_4$ as cooxidant in an optimized reaction medium (ethyl acetate–water) oxidize acyclic amides to imides.[374] The reaction rate is inversely related to the electron-withdrawing power of the acyl group, *i.e.* the electron density at the nitrogen atom (equation 57).



(56)



(57)

According to the same procedure, *N*-alkyllactams are converted to cyclic imides, where the position of the new carbonyl group depends on the ring size of the lactam.[375] Racemization of chiral *N*-acyl-pyrrolidines or -piperidines can be ruled out.[376,377]

Electrochemical anodic oxidation of amides and *N*-alkyllactams can be carried out with *N*-hydroxyphthalimide as mediator.[378] Oxidation takes place predominantly at the endocyclic carbon α to the nitrogen. The susceptibility of five-membered rings to oxidation is much higher than that of six-membered rings.

A photocatalytic oxidation takes place in a suspension of titanium(IV) oxide and five-membered or six-membered ring lactams.[379]

Reaction of nitrones with aroyl chlorides in the presence of triethylamine yields *N*,*N*-diacylamines (equation 58).[380] The reaction can be rationalized by formation of an aroyloxy(benzylidene)ammonium chloride, with elimination of the carboxylic acid and readdition of carboxylate to the nitrilium ion followed by 1,3-acyl shift to give the *N*,*N*-diacylamine.

Transition metal complexes are used as catalysts and as reagents in the synthesis of imides. Molybdenum hexacarbonyl activates strained aziridines and allows the nucleophilic attack of carbanions. Intramolecular rearrangement and a final oxidation yields imides completely stereospecifically (equation 59).[381] Dicobalt octacarbonyl catalyzes the conversion of β,γ-unsaturated amides to imides in the presence of carbon monoxide (equation 60).[382]

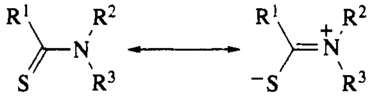
2.4.5 REFERENCES 432

## 2.4.1 INTRODUCTION

The size difference between carbon and sulfur atoms leads to relatively inefficient overlap of π-orbitals in the C=S bond. Consequently, thiocarbonyl compounds are in general highly reactive and have a tendency to di-, oligo- or poly-merize. This is particularly true for thioaldehydes, thioketones,[1] and thioketenes.[2] In contrast, thioamides (**1**) are usually perfectly stable and can be handled without problems. This stability can be understood in terms of a pronounced resonance interaction between the C=S π-bond and the nonbonding electron pair on nitrogen. The analogous electron delocalization prevails in thiolactams.[3]



(**1**)

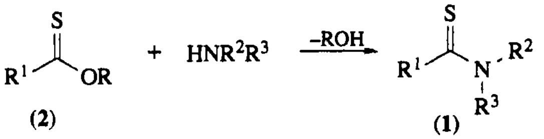
A large body of work has been directed toward synthesis and applications of thioamides.[4–7] The most important uses are as synthetic intermediates[5,8–10] and in heterocyclic synthesis.[5,11,12] Among the wealth of synthetic methods that lead to thioamides, thioacylation routes are certainly of prime importance.

Alternatively, for *N*-monosubstituted thioamides, methods based on nucleophilic addition of hydride, carbanions, or cyanide to isothiocyanates are available,[4,5,7] and, quite often, thionation of the corresponding amides provides a convenient route to thioamides (*cf.* Volume 6, Chapters 4.1 and 4.3).[13]

## 2.4.2 THIOACYLATION OF AMINES

### 2.4.2.1 Thioacylation with *O*-Alkyl Thiocarboxylates

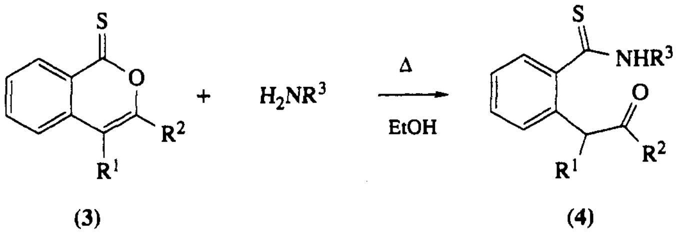
Nucleophilic attack of ammonia or of a primary or secondary amine on an *O*-alkyl thiocarboxylate (**2**) provides a formally straightforward approach to thioamides and a number of examples have been reported (equation 1).[14,15] However, some limitations should be noted. Thus, there is a tendency of esters (**2**) to rearrange to their *S*-alkyl isomers on heating (*cf.* Volume 6, Chapter 2.5)[15] and these yield amides with amines rather than thioamides. Besides, excess primary amine will lead to amidine formation, or the tetrahedral intermediate of the substitution reaction may break down to an imidate rather than a thioamide (*cf.* Volume 6, Chapter 2.7). These unwanted side reactions are favoured in polar, protic solvents such as ethanol. In contrast, THF has proven to be particularly useful in the synthesis of tertiary thioamides according to equation (1).[14] For improved reactivity in the preparation of *N*-aryl derivatives and milder reaction conditions, it is advantageous to employ the amine in the form of its Mg salt.[14]



(1)

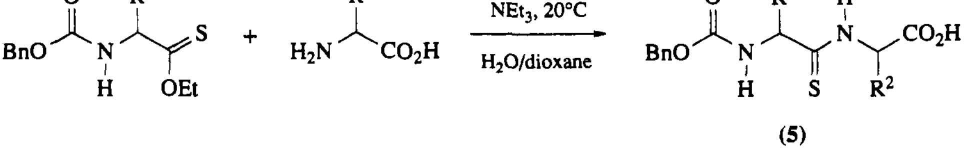
No activation is required in the synthesis of thioformamides using HCSOEt; this particularly reactive thioester allows one to work at 0 °C and offers the best route to the unsubstituted thioformamide (**1**; $R^1 = R^2 = R^3 = H$; 90%)[16] or *N*-alkylthioformamides.[16,17] This reagent has also been successfully employed in the thioformylation of hydroxylamines to give thioformohydroxamic acids (**1**; $R^1 = H$, $R^2 = OR^4$)[18] and, in a basic medium, also of hydrazines to give thioformohydrazides (**1**; $R^1 = H$, $R^2 = NR^4R^5$).[19]

Using primary aliphatic amines, ring opening of isocoumarin-derived thiolactones (**3**) according to equation (2) offers a convenient access to *o*-(2-oxoalkyl)thiobenzamides (**4**) with yields in the 80% range; aromatic amines give side reactions.[20]



(2)

*O*-Methyl thiocarboxylates are very suitable for the *N*-thioacylation of *N*-unprotected amino acids. Thus, shaking a heterogenous mixture of PhCSOMe in ether and the amino acid in aq. NaOH gives good yields of *N*-thiobenzoylated material.[21] Using *O*-alkyl thiocarboxylates of amino acids (**2**; $R^1 = R^2NHCHR^3$), the approach has been extended to synthesize endothiopeptides such as (**5**);[22-24] formation of imidates may interfere with the desired process.[23] The reaction has been carried out in water/THF using $Na_2CO_3$[24] or as shown in equation (3).[22]

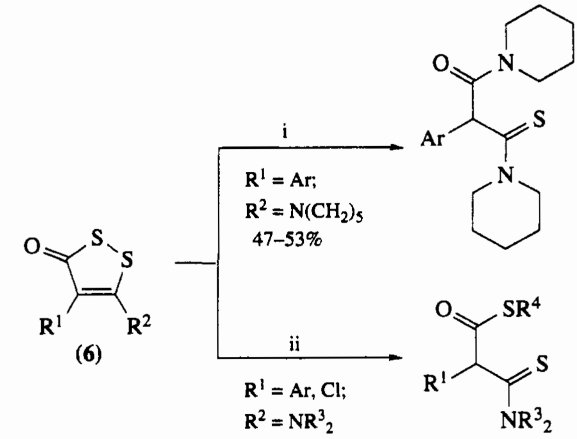


(3)

$R^1 = R^2 = Me$, 45%; $R^1 = Bn$, $R^2 = Me$, 57%

### 2.4.2.2 Thioacylation with 3*H*-1,2-Dithiol-3-ones

Cleavage of the S—S bond in 3*H*-1,2-dithiol-3-ones (**6**) by nucleophiles liberates the latent thioamide group. Piperidine in DMF or DMSO[25] and Grignard reagents[26,27] have been employed and allow synthesis of malonic acid monothioamides (Scheme 1).

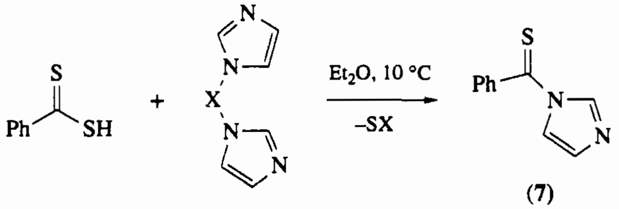


i, $HN(CH_2)_5$; ii, $R^4MgBr$ in THF, then quench with $H_2O$

**Scheme 1**

### 2.4.2.3 Thioacylation with Dithiocarboxylic Acids

Contrary to carboxylic acids which, under normal conditions, only give salts with amines, dithiocarboxylic acids, $RCS_2H$, are quite reactive in nucleophilic displacement reactions. However, the compounds are unpleasant to handle and, due to their limited stability, often give only low yields of thioamides in the reaction with amines.[1,28,29] The approach was successfully employed in the synthesis of thiobenzoyl azolides, *e. g.* in the formation of (**7**) according to equation (4).[30]



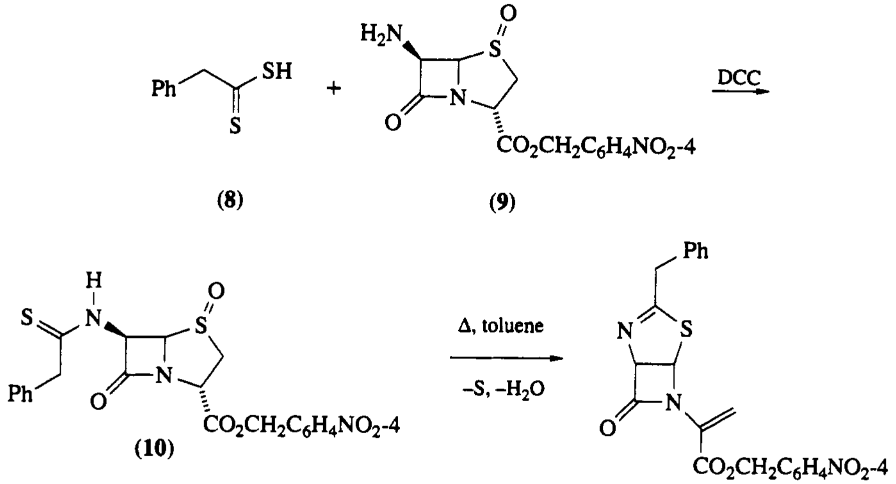
(**7**)

X = CO, 78%; X = CS, 77%; X = SO, 64% (4)

Phenyldithioacetic acid (**8**) allows thioacylation of the 7-amino group in penicillanate (**9**); the resulting highly nucleophilic thioamide (**10**) gives intramolecular trapping of the sulfenic acid, RSOH, which is in thermal equilibrium with the thiazolidine *S*-oxide moiety in (**10**; Scheme 2).[31]

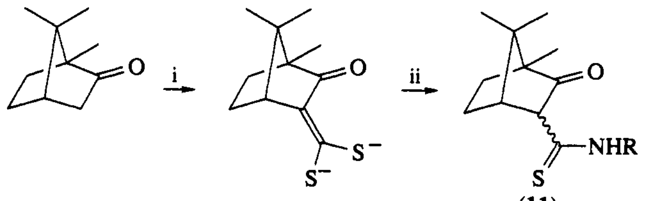
Thioacylation reactions with dithiocarboxylic acids are not limited to amines, but, employing the Mg salt, can also be carried out with hydroxylamine to give thiohydroxamic acids[18] or with hydrazine and some substituted hydrazines to provide thiohydrazides.[19]

The reaction of CH acidic compounds with $CS_2$ in the presence of excess base yields dianions of dithiocarboxylic acids.[32] Starting from camphor, neutralization with HCl and addition of primary amines yields 3-oxonorbornanethiocarboxamides (**11**) with undefined stereochemistry (Scheme 3).[33]



**(8)** **(9)** **(10)**

**Scheme 2**



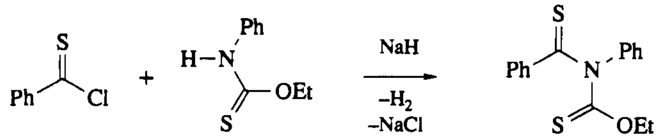
**(11)**

i, $NaNH_2$, $CS_2$; ii, HCl, then $RNH_2$ or $ArNH_2$ in $Et_2O$ or PhH

**Scheme 3**

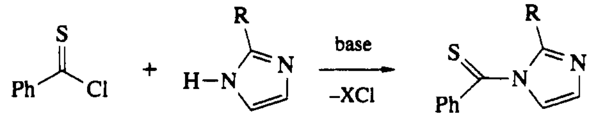
### 2.4.2.4 Thioacylation with Thioacyl Chlorides

Thioacyl chlorides, RCSCl, are powerful thioacylating agents as is obvious from the quantitative thiobenzoylation of the only moderately nucleophilic nitrogen in thiocarbamate (**13**; equation 5).[34] However, severe limitations are the difficult accessibility of thioacyl chlorides and their thermal lability.[35] Even if they are prepared from dithiocarboxylic acids using an improved procedure,[36] only thioaroyl chlorides, particularly PhCSCl (**12**), can be handled sufficiently easily to be used in synthetic work. Thus, various azoles react with (**12**) to furnish *N*-thiobenzoyl azolides (**14**) in the presence of excess azole or $NEt_3$ (equation 6); a particularly clean and fast reaction is achieved if *N*-silylated azoles are employed.[30] However, considering the fact that the chloride has to be prepared from the dithiocarboxylic acid, the approach of equation (4) presents a shortcut to the products.



**(12)** **(13)**

(5)



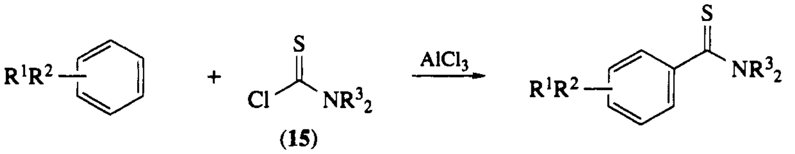
**(12)** **(14)**

R = H, 87%; R = Me, 47%

(6)

In contrast to thioacyl chlorides, thiophosgene, $CSCl_2$, is readily accessible and conveniently handled making it an important reagent in the synthesis of thiocarbamoyl chlorides (**15**; $ClCSNR_2$),[37] *O*-alkyl thiourethanes ($ROCSNR'_2$),[38] and thioureas ($R_2NCSNR_2$) (*cf.* Volume 6, Chapter 2.8).[39,40]

On the other hand, thiocarbamoyl chlorides (**15**) may be used in thioamide synthesis, though *via* carbon–carbon bond formation in Friedel–Crafts-type reactions (*cf.* Volume 2, Chapter 3.1). The approach is limited to fairly electron-rich aromatics such as alkylbenzenes, anisole, and furan, but fails for benzene; equation (7) gives some details.[41,42] Phenol does not require a Lewis acid catalyst in the reaction with $H_2NCSCl$, but gives a mixture of 2-/4-hydroxythiobenzamides along with *O*-phenyl thiocarbamate.[43]



(**15**)

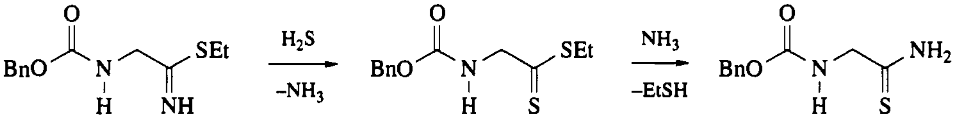
(7)

$R^1 = R^3 = Me, R^2 = H$, 53% (ref. 41); $R^1 = R^2 = Me, R^3 = H$, 61% (ref. 42);
$R^1 = OMe, R^2 = H, R^3 = Me$, 77% (ref. 41); $R^1 = R^2 = OMe, R^3 = Me$, 56% (ref. 41)

Another application of thiocarbamoyl chlorides (**15**) and related activated thiocarbonic acid derivatives in thioamide synthesis is found in their reaction with carbanions of highly CH acidic compounds $EWG_2CH_2$ to give thioamides $EWG_2CHCSNR_2$.[7,44]

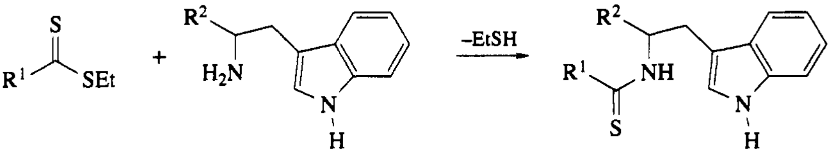
### 2.4.2.5 Thioacylation with Dithiocarboxylates

Dithiocarboxylates, $R^1CSSR^2$, give a faster reaction with amines than *O*-alkyl thiocarboxylates (**2**; *cf.* Section 2.4.2.1).[45] As shown in equation (8), this pronounced reactivity may lead to an undesired *in situ* reaction with the liberated ammonia to give a primary thioamide, when the ester is generated by thiolysis of a thioimidate.[23]



(8)

On the other hand, dithiocarboxylates allow the chemoselective thioacylation of the amine moiety in tryptamine or tryptophane (**16**; equation 9).[46]



(**16**)

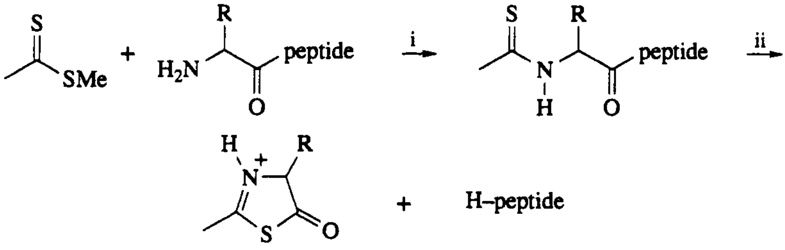
$R^1$ = Me, Br, Ph; $R^2 = H, CO_2Me$

(9)

Dithiocarboxylates are particularly useful reagents in the thioacylation of the terminal amino group in peptides. Combination with a subsequent cleavage by anhydrous TFA results in a modified Edman degradation[47] and a protocol has been worked out with conditions that are compatible with the ones required for an automatic sequential analysis (Scheme 4).[48]

By analogy with the reaction of equation (3) *N*-protected dithiocarboxylates of amino acids react with amino acids or peptides with a free $NH_2$ group to give endothiopeptides.[23,49] A systematic study of thio analogs of enkephalin revealed that attempted removal of benzyloxycarbonyl protective groups with HBr/HOAc results in decomposition, but that the t-BOC group can be cleanly cleaved from the product using liquid HF/anisole.[23] Therefore, dithiocarboxylates, t-$BOCNHCHR^1CSSR^2$, appear to be the reagents of choice in endothiopeptide synthesis.

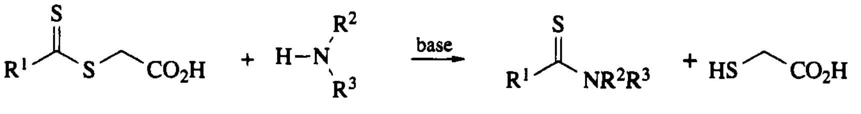
Thioamide synthesis from dithiocarboxylates and amines under basic conditions gives thiols as rather unpleasant parallel products. This problem is avoided by using *S*-thioacylated thioglycolic acids (**17**), as



i, $\text{NEt}_3$ or $\overset{+}{\text{H}}\text{NEt}_3\text{OAc}^-$ in DMF; ii, anhydrous TFA

Scheme 4

was first suggested by Holmberg.[50] As shown in equation (10) these esters display the usual reactivity of dithiocarboxylates,[28,51,52] but displacement reactions yield the thiol (**18**), which is soluble in aqueous base and so readily disposed of. However, esters (**17**) may fail to thioacylate sterically hindered amines and the derivative with $R^1$ = H is too labile to be used in thioformylations.

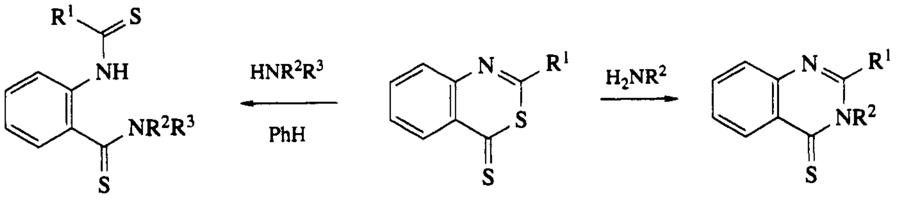


(10)

(**17**) (**1**) (**18**)

Several uses of the reaction in equation (10) for the *N*-thioacylation of amino acids, their esters, or amides have been reported.[21,53,54] It is noteworthy that these reactions occur without racemization allowing a CD study of *N*-thioacyl amino acids.[55] Moreover, the reaction of equation (10) is not limited to amines or amino groups, but has also been employed to thioacylate hydrazines and hydroxylamines to give thiohydrazides[19,56] and thiohydroxamic acids,[18] respectively.

In a heterocyclic environment, the dithiocarboxylate functionality may give a more complex reaction pattern, as shown by dithiolactones (**19**). Here, secondary aliphatic amines lead to ring cleavage providing 2-(thioacylamino)thiobenzamides (**20**),[57] whereas primary aliphatic or aromatic amines give thiolactams (**21**; Scheme 5).[58]



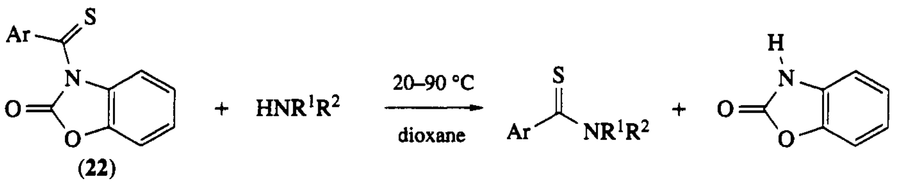
(**20**) (**19**) (**21**)

Scheme 5

In accord with the special reactivity of a dithiocarboxylate moiety, *O*,*S*-dialkyl dithiocarbonates, ROCSSR′, yield *O*-alkyl thiourethanes, ROCSNR′$_2$, on addition of amines.[38] Similarly, trithiocarbonates, $(\text{RS})_2\text{CS}$, yield thioureas.[39,40,59]

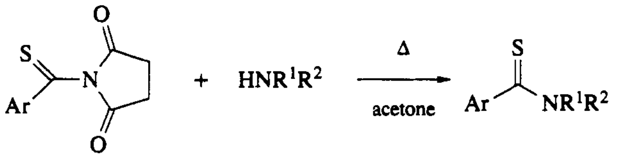
### 2.4.2.6 Thioacylation with Thioamides

Whether transamidation of a thioamide by addition of an amine is feasible depends on the interplay of the nucleophilicity of the incoming amine and the leaving-group ability of the amine to be replaced. The reaction is of particular importance in using some *N*-thioacylated heterocycles such as the benzoxazole derivative (**22**),[60] the succinimide (**23**),[61] and azoles (**24**) (equations 11–13).[30] The last mentioned approach appears to be the most general and proceeds under particularly mild conditions; in contrast to the reaction of equation (10), the method allows the thiobenzoylation of *N*-methylaniline, PhNHMe, using the imidazole derivative (**24**; $R^3$ = Me). The reactivity of the reagent can be further increased by employing azoles with more ring nitrogens and could be extended to the synthesis of thiohydrazides.[30]



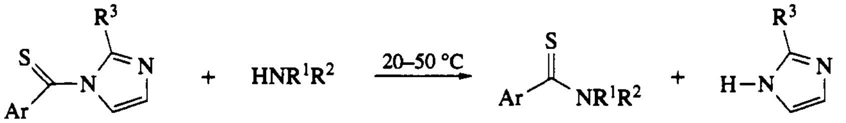
**(22)**

(11)



**(23)**

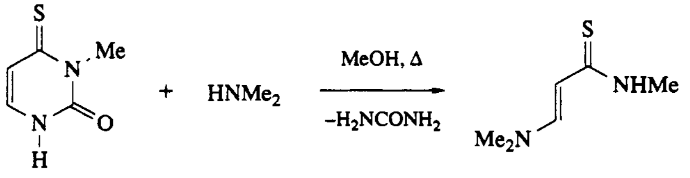
(12)



**(24)**

(13)

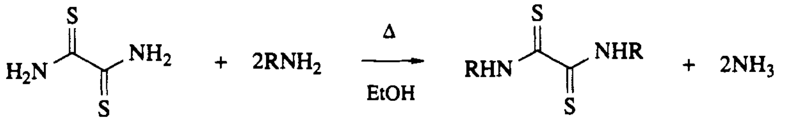
Cleavage of the *N*-acyl thioamide moiety in the 4-thiouracil (**25**) gives an example for the conversion of a thiolactam into a thioamide (yield 25%; equation 14).[62]



**(25)**

(14)

Heating of dithiooxamide (**26**) with primary amines yields the corresponding *N*-alkyl derivatives (**27**);[63] the reaction is catalyzed by acid with even $CO_2$ being effective (equation 15).[5,64]



**(26)** **(27)**

(15)

In a number of reactions thioamides are converted into other thioamides by C—C bond formation (Scheme 6). Examples from Seebach's umpolung chemistry include *C*-lithiation of $HCSNMe_2$ and subsequent reaction with electrophiles to give (**28**)[8] and deprotonation of one of the *N*-methyl groups in $Bu^tCSNMe_2$ and again electrophilic addition to yield products (**29**).[9]

Another possibility to obtain thioamides from thioamides is *via* electrophilic attack in the α-position (Scheme 6). Thus, aldol-type reactions are feasible and proceed with high *erythro* selectivity providing (**30**),[65] or even allowing optically active products (*cf.* Volume 2, Chapter 1.6).[66] Heating with a formamide *O,N*-acetal gives an α,β-unsaturated thioamide (**31**) in a sequence of electrophilic attack and elimination.[67,68]

Finally, thioamides can be modified *via* their *S*-silylated derivatives (**32**). With Lewis acid catalysis, addition of a Schiff base yields β-aminothioamides (**33**) as a mixture of diastereomers (Scheme 7).[69]

### 2.4.2.7 Thioacylation with Thioketenes or Thioketene Equivalents

Thioketenes (**34**) have a nonstabilized C═S group and consequently, except for sterically hindered examples,[70,71] exhibit a high tendency to oligo- or poly-merize.[2] Their application in synthesis depends on the availability of convenient routes to generate these species and, at least for the more elusive examples, trap them *in situ*. Recently, a number of routes to thioketenes have been developed, allowing them now to be considered as useful reagents.[2] The most handy methods to obtain thioketenes are based on: the flash-vacuum pyrolysis of 1,2,3-thiadiazoles (**35**);[72,73] the thionation of sterically hindered acyl chlorides (**36**);[70,71] the [3 + 2] cycloreversion of modified 2-alkylidene-1,3-dithiolanes (**37**);[74] and the 3,3-sigmatropic rearrangement of alkynyl allyl sulfides (**38**; Scheme 8).[75]

Thioketenes (**34**) are highly electrophilic and give a smooth reaction with ammonia or amines. In fact, addition of a secondary amine offers the best way to scavenge a suspected thioketene.[2] But the approach also deserves interest from the point of view of thioamide synthesis as it allows very mild and nonreducing conditions, tolerating the presence of sensitive additional functional groups such as cyano, nitro, or sulfonyl residues (equation 16).[74]

In the reaction of alkynyl thiolates (**39**) with excess diethylamine, the amine provides the proton to generate an aldothioketene (**40**) and, at the same time, serves as the trapping reagent (Scheme 9).[76]

Bis(trimethylsilyl)thioketene (**41**) gives a smooth reaction with amines, but one silyl group is always displaced in the process yielding thioamides (**42**; equation 17).[77]

Alknyl silyl sulfides, $R^1C{\equiv}CSSiR^2_3$, which are readily obtained by silylation of anions (**39**), react as thioketene equivalents. Thus, β-thiolactams are formed in the reaction with C═N systems (*cf.* Volume 5, Chapter 2.2)[3] and thioamides on addition of amines;[78,79] equation (18) shows a typical example.[79] This approach has great promise for the thioacylation of very sensitive natural products.

### 2.4.2.8 Thioacylation with Carbon Disulfide

At elevated temperatures and under pressure, carbon disulfide converts triethylamine into thioformamide (**43**) in 49% yield (equation 19); similarly, the reagent yields thioformamides (23–36%) from the corresponding amides.[80]

Use of carbon disulfide has particular significance for the synthesis of dithiocarbamates[82] and thioureas in thioacylation reactions.[39,40,82]

## 2.4.3 THIOLYSIS OF IMIDOCARBOXYLIC ACID DERIVATIVES

### 2.4.3.1 Thiolysis of Imidoyl Chlorides

Thiolysis of imidoyl chlorides offers a straightforward route to thioamides. The formation of *N*-sulfonyl thioamides (**47**) in equation (21) gives an example,[83] but the method works particularly well for the synthesis of *N,N*-disubstituted thioamides including thiolactams from the corresponding imidium chlorides, $R^1C({=}NR^2)Cl$.[84] Quite often, the chlorides are generated *in situ* from the corresponding amides by the action of $COCl_2$ so that the overall process represents an alternative to the thionation of amides.[13] In a useful modification, $HS(S)P(OEt)_2$ is used to achieve the thiolysis and allows very high yields of thiobenzamides and of dithiooxamides; nitro-substituted derivatives are not reduced under the reaction conditions.[85] Thiourea has been employed to convert α-chlorine-substituted azines (**48**) into thiolactams (**50**); as shown in equation (22), thiuronium salts (**49**) are supposed to be intermediates in this transformation.[86]

The thiolysis of imidoyl chlorides has proven to be particularly useful in the synthesis of α-chlorothioamides. Thus, chlorine can be added to trichlorovinylamines (**53**) and the resulting imidium salt (**54**) thiolyzed to give trichlorothioacetamides (**55**; equation 24).[88] Similarly, addition of HCl and $H_2S$ to di- or tri-chlorovinylamines (**53**) yields tertiary mono- and di-chlorothioacetamides, respectively.[88] In a recent modification, α,α-dichlorination of propionimidium salt (**56**) giving (**57**) is achieved and, subsequently, thiolysis and dehydrohalogenation using $AlCl_3$-modified triethylamine to obtain α-chlorothioacrylamides (**58**; equation 25).[89]

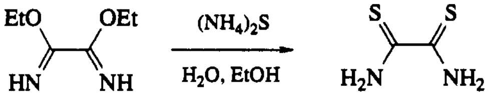
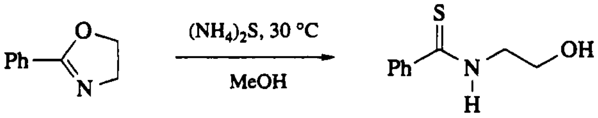
### 2.4.3.2 Thiolysis of Imidates

The most common source of imidates is nitriles (*cf.* Volume 6, Chapter 2.7) and, as these can be directly transformed into thioamides (*cf.* Section 2.4.3.4), this one-step approach is usually preferred. Moreover, depending on the reaction conditions and the substitution pattern, thiolysis of imidates may give thioesters rather than thioamides (*cf.* Volume 6, Chapter 2.5).[21] However, some high-yield applications of imidates in thioamide synthesis have been reported and are detailed in equations (27)[90] and (28).[91]



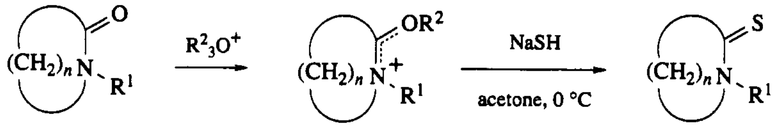
(26)

(27)



(28)

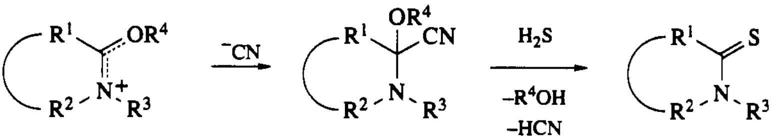
*N*-Substituted thiolactams (**65**) are obtained from lactams (**63**) in 55–100% yield by alkylation with Meerwein reagent and subsequent thiolysis of the resulting imidium salt (**64**; equation 29).[92] The approach has been extended to other thiolactams and acyclic examples employing a cyanohydrin derivative (**66**; equation 30).[93] Similarly, *N*,*N*-acetals of formyl cyanide, $(R_2N)_2CHC{\equiv}N$, yield thioformamides on treatment with $H_2S$.[94]



(63) (64) (65)

$R^1$ = Me, $(CH_2)_3F$; $R^1 \neq$ H; $n$ = 3, 4

(29)

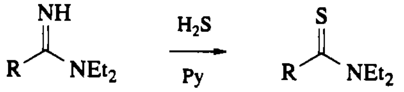


(66)

(30)

### 2.4.3.3 Thiolysis of Amidines

Thiolysis of *N*-monosubstituted amidines, $R^1C({=}NH)HNR^2$, proceeds unselectively giving a mixture of thioamides $R^1C(S)NH_2$ and $R^1C(S)NHR^2$.[95] However, *N*,*N*-disubstituted examples (**67**) can be cleanly transformed into tertiary thioamides (**68**; equation 31).[95]



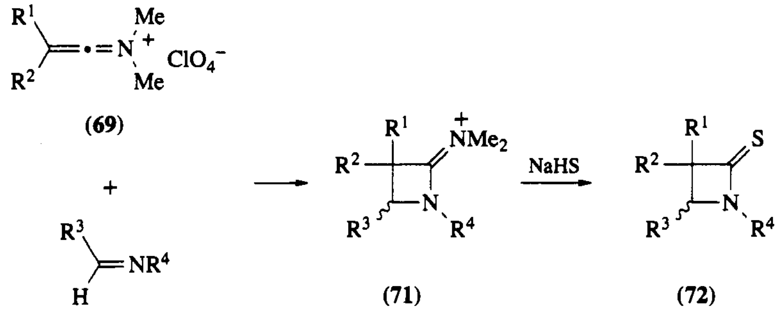
(67) (68)

(31)

Cyclic amidinium salts (**71**) are obtained by [2 + 2] cycloaddition of ketenimmonium compounds (**69**) to Schiff bases (**70**; $R^3$ = H, Ph, $MeO_2C$) or thioimidates (**70**; $R^3$ = SBn); their thiolysis provides an elegant access to β-thiolactams (**72**; equation 32).[96]

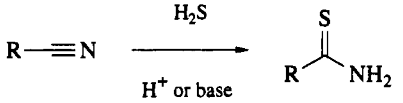
### 2.4.3.4 Thiolysis of Nitriles

Addition of $H_2S$ to nitriles (**73**) represents an important method for the synthesis of primary thioamides (**74**; equation 33). The reaction is carried out under base or acid catalysis. The base-catalyzed process is particularly useful in the preparation of aromatic thioamides, *i.e.* for R = aryl, hetaryl in (**73**); triethylamine in molar proportion or pyridine, which at the same time also serves as solvent, are employed most commonly.[97] The approach tolerates the presence of various other functionalities such as an amide,[98] hydrazone,[99] enamine,[68] α-oxo,[100] α-acetoxy[101] or α-amino group.[102] Moreover, the reaction has been applied to the synthesis of thioasparagine as such[103] or incorporated into a dipeptide, as shown

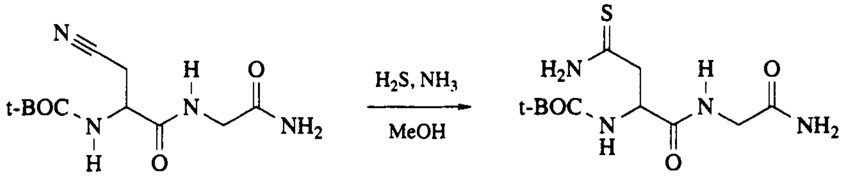


**(69)** **(70)** **(71)** **(72)** (32)

in equation (34).[104] Alternatively, a basic ion-exchange resin in methanol has been suggested to catalyze the transformation of nitriles (**73**) into thioamides (**74**).[105]

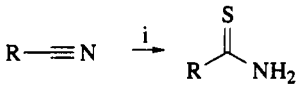


**(73)** **(74)** (33)



(34)

Without special measures, aliphatic nitriles (**73**; R = alkyl) often give low yields in the base-catalyzed thiolysis.[106] It has proven advantageous to work in the presence of diethylamine, a tetraalkylammonium hydroxide, or a guanidine derivative in DMF, DMSO or sulfolane; these conditions allow one to work at atmospheric pressure and provide aliphatic thioamides in medium to good yields.[107] However, as detailed in Scheme 10, pressure is required in the phase transfer modification of the reaction which gives excellent yields for aromatic (R = Ph, 3-pyridyl) and moderate to good yields starting from aliphatic substrates (R = Bn, Pr).[108] Similarly, 13–17 atm of $H_2S$ are a prerequisite in the synthesis of thioformamide, $HCSNH_2$, from HCN with addition of triethylamine[109] or of a basic ion-exchange resin.[110] In the presence of the $Cu(NH_3)_4^{2+}$ cation, NaCN reacts with $H_2S$ to yield 77% dithiooxamide (**26**).[111]

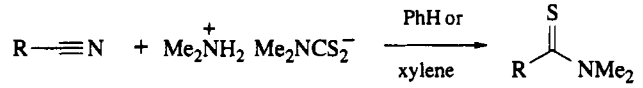


**(73)** **(74)**

i, $Na_2S$, $H_2S$ (2 atm), $R'_4NCl$ or dibenzo-18-crown-6 in $H_2O$, PhH

**Scheme 10**

According to equation (35), heating of nitriles (**73**) with dithiocarbamate (**75**) gives up to 80% of *N*,*N*-dimethylthioamides (**76**).[112] In a related reaction, *N*-mono- and *N*,*N*-di-substituted thioformamides are isolated on heating HCN and $H_2S$ in the presence of an amine.[94,109,113]



**(73)** **(75)** **(76)** (35)

The thiolysis of nitrile groups can also be applied to cyanamides giving thioureas.[39,40,114]

In the acid-catalyzed thiolysis of nitriles (73) $H_2S$ is commonly replaced by appropriate precursors or equivalents. Thus, thioacids, RCOSH, have been used together with HCl[115] or $SnCl_4$.[116] Thioacetamide (77) is a very convenient source of $H_2S$; as shown in equation (36), an equilibrium is established which is shifted to the right, if the liberated MeCN is removed by distillation.[117] Alternative sources of $H_2S$ are dithiophosphoric, $HSP(=S)(OR)_2$ with R = Et[118] or $Pr^i$,[119] or phosphinodithioic acid derivatives, $HSPPh_2(=S)$.[120] The last mentioned approach allows the elegant synthesis of α-hydroxythioamides (78) in Scheme 11.[121]

Heating of $P_4S_{10}$ with nitriles (73) yields adducts incorporating a $P_4$ tetrahedron; hydrolytic cleavage furnishes thioamides.[122]

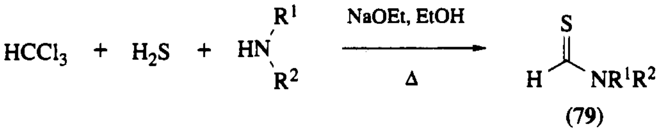
**Scheme 11**

## 2.4.4 THIOLYSIS OF 1,1,1-TRIHALIDES

In a process reminiscent of isonitrile hydrolysis, dichlorocarbene as generated from $CHCl_3$ reacts with $H_2S$ in the presence of primary or secondary amines to yield thioformamides (79; equation 37).[123] If pressure is employed, $CCl_4$ or $Cl_3CCCl_3$ can also be used with the latter giving dithiooxamides (27), *e.g.* with $BuNH_2$, 65% of BuNHCSCSNHBu.[124]



(37)

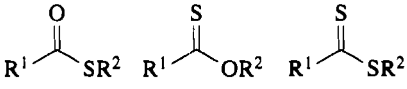
## 2.5.1 INTRODUCTION

Three different types of thiocarboxylic esters (and also thiolactones) exist: the thiol, thioxo- and dithioesters which, according to the IUPAC rules, are named *S*-alkyl (*S*-aryl) carbothioates (**1**), *O*-alkyl (*O*-aryl) carbothioates (**2**) or alkyl (aryl) carbodithioates (**3**). Acylation-type reactions were used for the first preparations of thiol carboxylic esters (**1**) by Tjuttschew (1863),[1] Saytzeff and Lukaschewicz (1868)[2] and Michler (1875).[3] Thioxocarboxylic esters (**2**) were first obtained *via* an acylation route by Matsui (1908).[4] On the other hand, alkyl dithiobenzoates (**3**; $R^1$ = Ph), which were first mentioned in a patent by Bloch and Höhn (1908),[5a] and alkyl alkanedithioates (**3**; $R^1$ = Me, Et, $PhCH_2$), first described by Houben and Schultze (1910),[5b] were prepared by alkylation of the corresponding metal carbodithioates.



**(1)** **(2)** **(3)**

Some structural characteristics and significant spectroscopic properties of thiocarboxylic esters are compiled in Table 1. These data might be helpful for preparative work. The IR frequencies of the CX—SR group are especially indicative of a thioester even if strong vibrational coupling occurs, as in the case of (**2**) and (**3**). The best and unequivocal spectroscopic feature is the $^{13}C$ NMR signal of the CX carbon atom. The CS groups of thioxo- (**2**) and dithio-esters (**3**) can be distinguished in most cases since the chemical shifts are clearly different. It should be mentioned, however, that the intensity of the signals is sometimes extremely low and the lines can thus be detected only at high signal-to-noise ratios.

**Table 1** Physical and Spectroscopic Data of Thiocarboxylic Esters

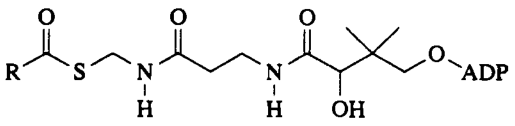
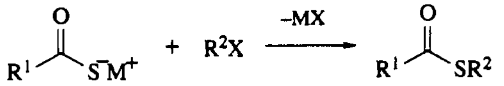
Thiocarboxylic esters do not play a major role in biochemistry, with the one exception of acetyl-CoA (**4**; R = Me), the prototype of acyl-CoAs (**4**), which represent important energy rich intermediates in amino acid, lipid and glucose metabolism.[23] In fact the thiol esters (**4**) fit in with the scope of this chapter. They are often formed by acylation reactions and themselves react as acylating agents.

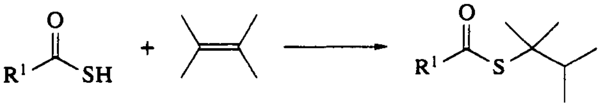


(**4**)

Although acylation reactions rank among the best-known methods for the synthesis of thiocarboxylic *S*-esters (**1**), there exist other important and convenient routes,[6,24] *e.g.* the alkylation of thiocarboxylate anions (equation 1) or radical addition of thiocarboxylic acids to carbon–carbon double bonds (equation 2). These methods are not dealt with here (*cf.* Volume 4, Chapter 1.5).

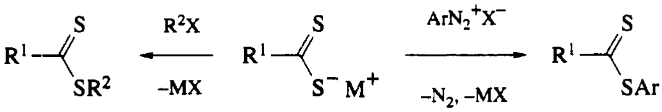


(1)



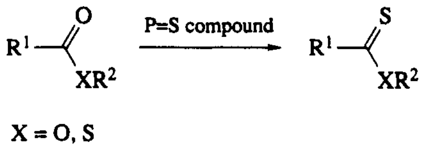
(2)

Alternatives to the acylation-type reaction are even more important in the thioxo- and dithio-carboxylic ester series[6,14,15,24–29] since dithiocarboxylate salts are most conveniently obtained from a variety of precursors and can be not only alkylated but also arylated by arenediazonium hydrogen sulfates (equation 3).[14,30] An advantage of the latter method is that no thiophenols are needed, which are necessary, but sometimes not easily obtained, educts in most other *S*-aryl thiocarboxylate preparations (*cf.* Chapter 1.5).



(3)

In the last decade the methods of converting carbonyl to the corresponding thiocarbonyl compounds have been substantially improved.[6,15,25–28] Therefore, thioxo- as well as dithio-carboxylic esters are accessible from esters, thiol esters and even carboxylic acids by reacting them with phosphorus pentasulfide or 1,3,2,4-dithiadiphosphetane 2,4-disulfides such as Lawesson's[19] or Davy's[31] reagent (equation 4; *cf.* Chapter 4.1, this volume).



(4)

Finally, sigmatropic processes (*cf.* Volume 5, Part 7) are useful procedures for the preparation of certain thioxo- and dithio-carboxylic esters.

## 2.5.2 THIOL ESTERS AND THIOL LACTONES

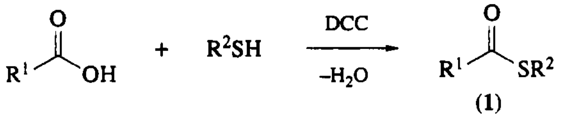
Thiol carboxylic esters (**1**) are the most common compounds among the three types of thioester. They are activated derivatives of carboxylic acids and exhibit acylating properties similar to those of carboxylic acid anhydrides. They have therefore found widespread application in synthetic chemistry and have been used for preparing esters, amides and peptides, especially macrocyclic ketones and lactones. Several review articles concerning the chemistry of thiol carboxylic esters[6,24,32,33] and thiol lactones[34] have appeared.

### 2.5.2.1 Acylation of Thiols with Carboxylic Acids

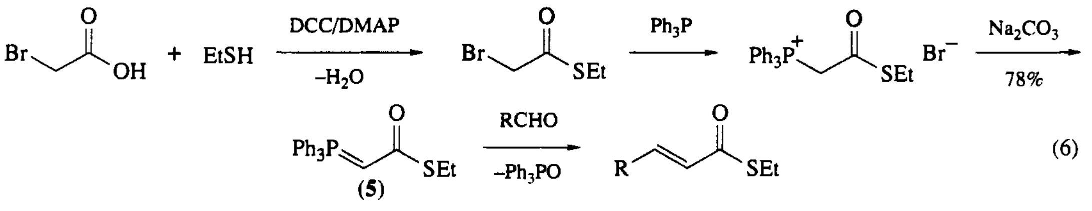
Unlike carboxylic esters, open-chained *S*-alkyl thiocarboxylates cannot be obtained by direct proton-catalyzed esterification. Whereas thiocarboxylic acids react with alcohols to form esters as expected, thiol esters are formed on reaction of carboxylic acids with thiols, but the equilibrium is shifted towards the educts and the reaction is not useful for synthetic purposes. Therefore, activation is necessary and several methods have been developed to meet this requirement.

Condensing agents that are well known for peptide synthesis are also very suitable for the preparation of thiol carboxylic esters.

DCC can be used to prepare *S*-alkyl and *S*-aryl thiocarboxylates (**1**) from carboxylic acids and thiols according to equation (5).[35] This method has been successfully applied to the synthesis of thiol esters with sensitive substituents, *e.g.* *S*-methyl thioacrylate, a natural product.[36] In particular, *N*-protected amino acid and peptide *S*-phenyl esters, which are useful building blocks in peptide synthesis, are obtained in excellent yields without racemization.[37] *N*-Hydroxyphthalimide[38] and DMAP[39] have been used as cocatalysts to facilitate the reaction. The preparation of the Wittig reagent (**5**) by this route[39] is shown in equation (6).

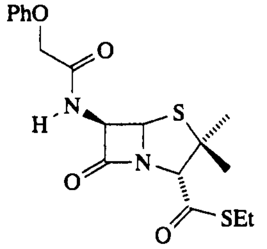


(5)



(6)

Activation of the carboxyl group is also achieved by various phosphorus compounds (**6**–**16**; *cf.* Table 2). Obviously, mixed anhydrides are the reactive intermediates, but these need not be isolated. The yields are generally high. *S*-Alkyl monothiomalonates and *S*,*S*′-dialkyl dithiomalonates are obtained by means of (**15**). *N*-Protected amino or hydroxy as well as 6-acylaminothiopenicillanic acids (**17**) can be converted to the corresponding thiol esters without racemization if (**11**), (**12**) or (**13**) are used as activators. Steric hindrance by bulky groups $R^1$ or $R^2$ during the formation of the carbon–sulfur bond in (**1**) is overcome by using (**8**), (**9**) or (**13**) as catalysts. This is important since the *t*-butylthiocarbonyl group is a good protecting group during the synthesis of macrocyclic lactones.[42,51,52] Antibiotics of the macrolide type have also been prepared *via* thiol esters, which were obtained by selective activation of the corresponding ω-hydroxycarboxylic acids with carbonyldiimidazole or similar reagents.[53–56]



(**17**)

**Table 2** Phosphorus Compounds $R^1R^2P(O)X$ used as Activators for the Preparation of Thiol Carboxylic Esters (**1**)

[a]2-Oxo-2,3-dihydro-1,3-oxazolyl; [b]$(PhS)_3PS$/imidazole.

2-Halo-pyridinium or -benzothiazolium salts[56,57] have been applied in the preparation of *S*-alkyl or *S*-aryl carbothioates from carboxylic acids *via* acyloxypyridinium salts (*cf.* equation 7).

Another efficient method seems to be Mukaiyama's[58] redox condensation, which has found widespread application in total syntheses of natural products. Originally *S*-(2-pyridyl)carbothioates (**18**), obtained from carboxylic acids, 2,2′-dipyridyl disulfide and triphenylphosphine (equation 8), were used in follow-up reactions.[59] The use of (**18**) has been reviewed in the literature.[51,52,60–63]

Carboxylic esters, especially lactones, are conveniently obtained *via* the pyridyl thioesters (**18**). Some examples are given in Scheme 1.[64] The 2-pyridyl thiol ester method can be further improved if silver ions ($AgClO_4$) are used as activators.[65] Corey and Brunelle[66] have also introduced other heterocyclic disulfides, and (**19**) was found to be superior to other reagents tested for the formation of lactones from ω-hydroxyalkanoic acids.

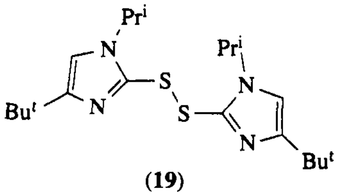
**Scheme 1**



**(19)**

Grignard reaction of (**18**) yields open-chained as well as cyclic ketones, including natural products such as jasmone, in a selective way since formation of carbinols or Claisen-type condensation products is completely inhibited (equation 9).[58,67]

The use of diphenyl disulfide in the presence of triphenylphosphine to prepare thiol carboxylic esters has been described in the recent literature[68] and even *S*-alkyl alkanethioates can be obtained in good yields if DMAP is used as the base in the second step (*cf.* equation 10).[69]

*S*-Methyl[70] and *S*-aryl[71] thiocarboxylic esters can also be prepared directly from carboxylic acids if thiocyanates or chlorothioformates[72] are used instead of thiols (equations 11 and 12).

Finally, it should be mentioned that γ- and δ-thiol lactones are in many cases formed simply by heating the corresponding mercaptocarboxylic acids[34] or by treating them with phosphorus pentoxide.[73] The β-thiolactone (**20**) has also been obtained by flash pyrolysis of 3-mercapto-2-naphthoic acid (equation 13).[74]

## 2.5.2.2 Acylation of Thiols with Acyl Halides

Reaction of thiols or thiolates with acyl halides, chlorides in particular, represents the standard method for preparing thiol carboxylic esters (*cf.* ref. 33 and the literature cited therein). Since thiols are strong nucleophiles, the acylation even takes place in the absence of base. However, to obtain excellent yields under mild conditions, tertiary amines are added or metal (Si, Sn, Tl$^{I}$ Cu$^{I}$) derivatives of the thiols are used. The following examples demonstrate the scope of the method.

Thallium(I) thiolates have been introduced by Masamune *et al.*[75,76] Their use is especially advantageous if *S*-*t*-butyl thiocarboxylic esters are to be prepared which can serve as educts for macrolide synthesis. Zearalenone dimethyl ether ethylene acetal (**22**; *cf.* also Scheme 1) was obtained from the corresponding acid chloride and thallium(I) α-methylpropanethiolate *via* the *S*-*t*-butyl benzenecarbothioate (**21**; equation 14)

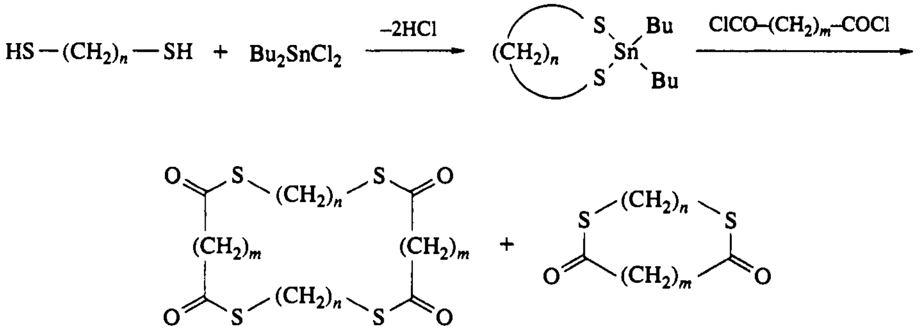
Stannyl thiolates[33,78] were recently shown to be applicable to the formation of the macrocyclic polythiolactones (**23**) and (**24**), according to equation (16).[79]



(**23**) (**24**)

(16)

Several optically active *S*-(2-methylbutyl) alkanethioates (**25**)[80] and the naturally occurring thiocarboxylic esters (**26**)[81] and (**27**)[82] were synthesized from the corresponding acid chlorides and thiols, as well as *S*-phenyl arenecarbothioates and thiocinnamates, which are applicable for the preparation of radio-labeled CoA derivatives (**14**; equation 17),[83] and the acyl sulfenates (**28**) occurring in the cultural media of *Pseudomonas* species (equation 18).[84]

(18)

Special thiol carboxylic esters (**29**) were prepared from aroyl halides and arene thiolates.[85] These 4,4′-disubstituted *S*-aryl arenecarbothioates might gain importance from a practical point of view, since they exhibit liquid crystal properties and could be useful as components of a display cell. Another thiocarboxylic ester (**30**), which was obtained from a zinc thiochelate and benzoyl chloride (equation 19),[86] might be potentially useful as a precursor for organic conductors.

Thiol carboxylic esters of an unusual type are formed if thioamides react with acyl chlorides. 2-Acylthiopyridine *N*-oxides, which are yellow crystalline compounds, are the primary reaction products

of *N*-hydroxy-α-thiopyridone and acyl chlorides. They undergo spontaneous rearrangement to yield the *N*-acyloxy-α-thiopyridones (**31**), which are new and versatile sources of alkyl radicals for use in organic synthesis. Reductive decarboxylation of (**31**) takes place on photolysis or thermolysis in the presence of a suitable hydrogen donor HX (*e.g.* $Bu^tSH$) and alkanes $R^1H$ are formed in high yields (Scheme 2).[87] Addition of electron poor alkenes leads to products (**32**) in which a carbon–carbon and a carbon–sulfur bond have been formed (Scheme 2).[87] The related 2-acylthio-*N*-alkylpyridinium salts (**33**) can serve as water soluble acylating agents for phenols, amines or carboxylic acids according to equation (20).[88]

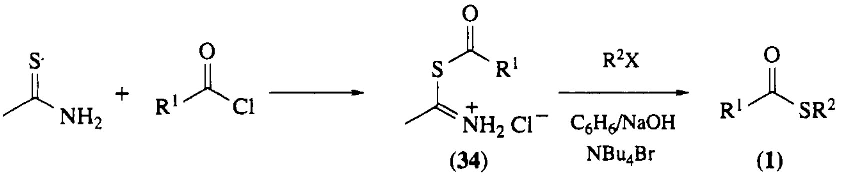
The open-chained thioacetamide, on the other hand, yields iminium salts (**34**) on acylation. Reaction of (**34**) with alkyl halides and subsequent hydrolysis results in the formation of thiocarboxylic esters (**1**).[89] This reaction is actually performed in one step under phase transfer catalysis (equation 21). No unpleasant smelling thiols or thiocarboxylic acids are required as educts, the yields are high and a large variety of substituents $R^1$ and $R^2$ are possible.[89]



(21)

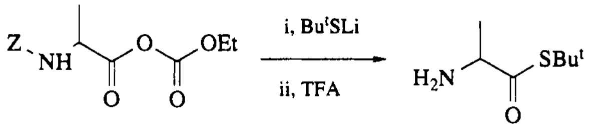
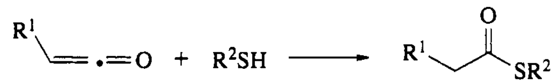
### 2.5.2.3 Acylation of Thiols with Anhydrides, Ketenes and Esters

Acid anhydrides in the presence of basic catalysts can be used instead of acyl chlorides in acylation reactions of thiols.[33] Mixed anhydrides of *N*-protected amino acids and ethyl carbonate yield the corresponding *S*-*t*-butyl thiocarboxylic esters, which are useful reagents for peptide syntheses (equation 22).[90]

Acylation of thiols with ketenes (equation 23) is a method of long standing.[33] In many cases the yields are nearly quantitative. Functionalities such as acetamino groups or carbon–carbon double bonds in the thiol are not attacked under the mild reaction conditions and optically active thiol esters are obtained without racemization.[33,78]



(22)



(23)

Metal thiolates or benzenethiols in the presence of triethylamine also react very smoothly with diketene to yield *S*-alkyl (**35**)[91] or *S*-aryl acetothioacetates (**36**).[92] The β-keto thioesters (**35**) can be used in exceptionally mild preparations of β-keto amides (**37**),[93] whereas (**36**) can be cyclized by Lewis acids to form thiocumarins (**38**).[92] The *S*-*t*-butyl thiol ester (**35**) is also a suitable substrate for *C*-alkylation in the β-position or, after double deprotonation, in the δ-position (Scheme 3).[91]

Acylation of a simple thiol with an alkyl carboxylate is not a very suitable method for preparation of *S*-alkyl thiocarboxylates. Transesterification is, however, possible if either the thiol or the carboxylic ester is activated. The enhanced reactivity of boron, aluminum and silicon thiolates has been utilized for the synthesis of a large variety of thiocarboxylic *S*-esters, including hydroxy derivatives (from lactones).[33] α,β-Unsaturated thiol esters, *e.g.* cinnamoyl or 2-butenoyl derivatives, are also accessible. Michael addition, an undesirable side reaction of thiols, is completely avoided if alkyl trimethylsilyl sulfides or tris(arylthio)boranes are applied.[33]

Phenyl carboxylates are reactive enough to form thiocarboxylic esters directly with thiols or thiolate anions.[33] This reaction was applied for the preparation of polyhexamethylene thioterephthalates (equation 24).[94]

The highly activated 4-acyloxypyridines react with thiols under particularly mild conditions (room temperature, no acids or bases) to form *S*-alkyl or *S*-phenyl carbothioates in excellent yields (equation 25).[33,95]

As expected, formation of five- and six-membered thiolactones is a favored process. It occurs easily therefore, even with unactivated esters,[34] as for instance in the case of thiocumarins (**38**) and dihydrothiocumarins (**39**; Scheme 4).[96]

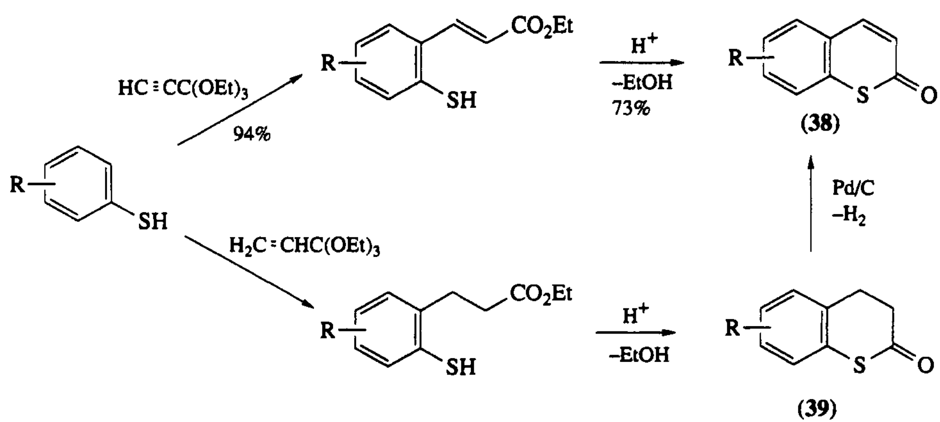
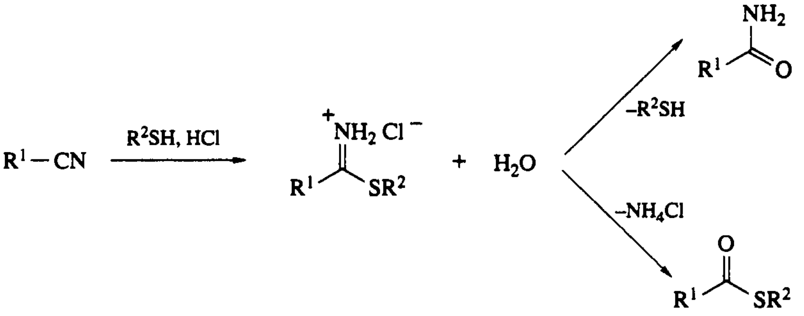
(25)

### 2.5.2.4 Acylation of Water (Hydrolysis) with Imidothioates, Thioorthoesters and Ketene *S,S*-Acetals

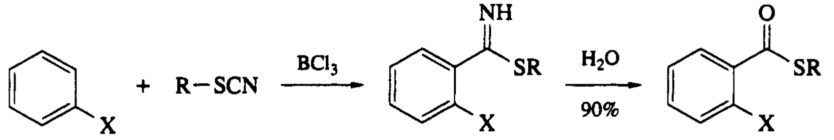
Imidothioates are easily accessible from nitriles (equation 26)[6] or, in special cases, from alkyl thiocyanates (equation 27).[97] Their hydrolysis represents a route to thiol carboxylic esters.[6,33,97] However, the alternative, formation of amides, is not easy to avoid and the yields are therefore often low.[33,98]



Scheme 4



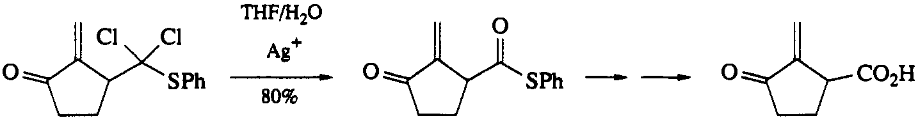
(26)



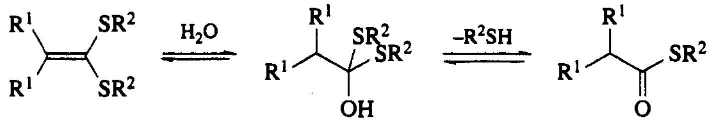
(27)

Thioorthoesters[6] as well as α,α-dihalo sulfides and related compounds may be partially hydrolyzed to yield thiol carboxylic esters.[99] This reaction has been utilized in a sarcomycin synthesis (equation 28).[99]

Ketene *S*,*S*-acetals are also hydrolyzed with aqueous acid *via* dithioorthoesters as has been shown recently,[100] and thiol carboxylic esters are obtained in good yields (equation 29).[6]



(28)

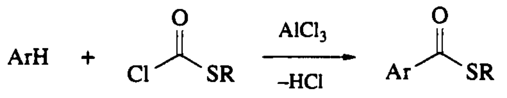


(29)

### 2.5.2.5 Acylation of Arenes and Carbanions under Formation of Carbon–Carbon Bonds

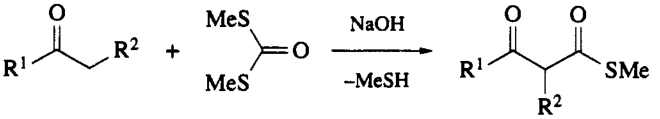
Although reactions of this type are dealt with in other volumes or chapters of this book, a short overview should be given here because in some cases they represent interesting and useful methods for the synthesis of thiol carboxylic esters.

Friedel–Crafts acylation of arenes (*cf.* Volume 2, Chapter 3.1) can be achieved with *S*-aryl or *S*-*n*-alkyl chlorothioformates in good to moderate yields (equation 30).[33]



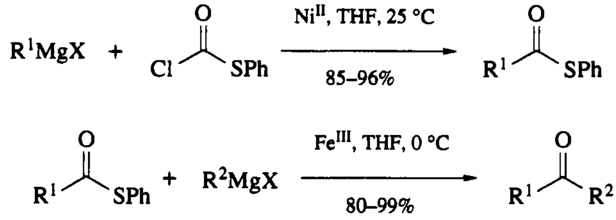
(30)

*S*,*S*-Dimethyl dithiocarbonate also reacts with carbonyl-stabilized carbanions (equation 31).[33]



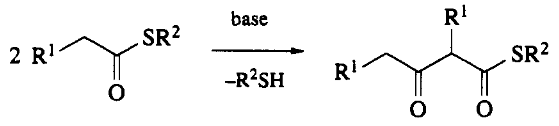
(31)

The Grignard reaction (*cf.* Volume 1, Chapter 1.16) was recently used in a highly efficient route to ketones through sequential coupling of *S*-phenyl chlorothioformate in the presence of transition metal catalysts (equation 32).[101]

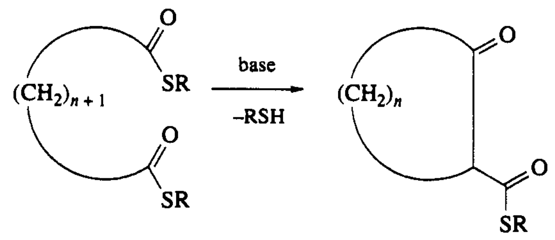


(32)

Claisen (*cf.* Volume 2, Chapter 3.4) and Dieckmann (*cf.* Volume 2, Chapter 3.5) condensation reactions work well with thiocarboxylic esters (equations 33 and 34).[33]



(33)



(34)

Magnesium or lithium enolates of thiol carboxylic esters can be acylated with suitable reagents (*cf.* Volume 2, Part 1).[33] Highly functionalized new derivatives are obtained. The example shown in equation (35)[33,102] is closely related to the *C*-acylation of malonyl-CoA with acetyl-CoA, which plays an important role in the biosynthesis of polypeptides and fatty acids. (*S*)-4-Hydroxy-5-methyl-3-oxo-hexanoyl-L-leucine esters (**41**), 2-demethyl analogs of the Hip-Leu moiety of didemnin antibiotics, can be prepared *via* the β-keto thiol carboxylic esters (**40**; equation 36).[103]

*S*-Alkyl arenecarbothioates (**42**), on the other hand, undergo deprotonation at the *S*-alkyl group. The resulting dipole-stabilized carbanions may be acylated by the starting compound (**42**) to form *S*-(2-oxoalkyl) arenethioates (equation 37).[33]

## 2.5.3 THIOXOESTERS AND THIOXOLACTONES

Thioxocarboxylic esters are the least conveniently available type of thioester because of their decreased stability. Oxidation or hydrolysis to form the corresponding esters occurs very easily and thiol esters are formed by rearrangement. On the other hand, the pronounced reactivity makes them promising candidates for synthetic utilization. This valuable chemical property of thioxocarboxylic esters has only

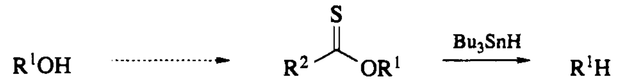
**(42)**

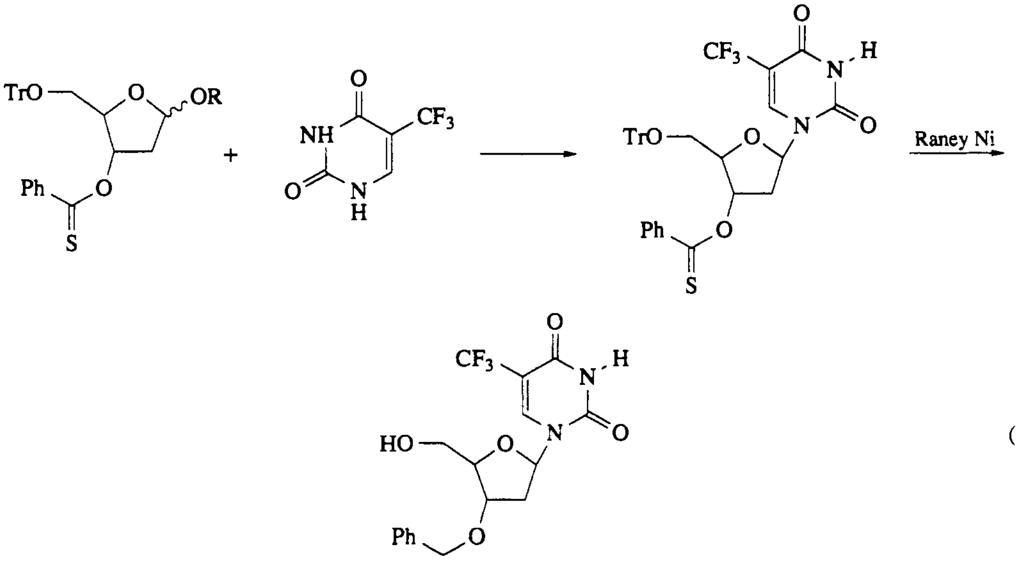
(37)

recently attracted attention. Primary, secondary and tertiary alcohols are, for instance, reducible to the corresponding hydrocarbons *via* thioxoesters (equation 38).[28,104]



(38)

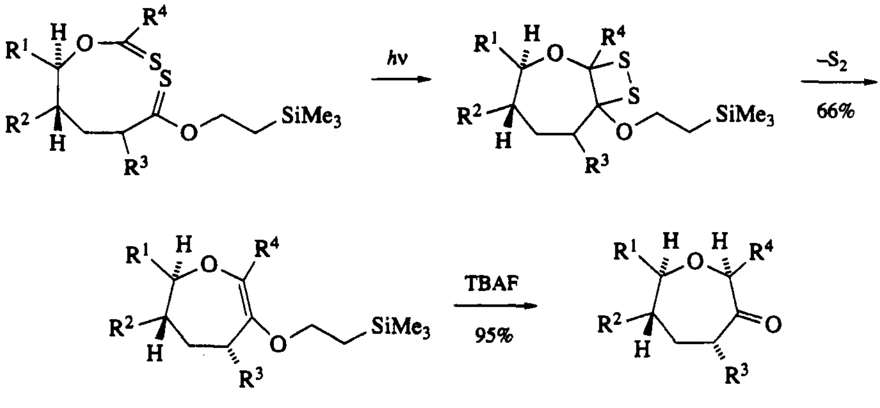
Reductive desulfurization of the thiocarbonyl group with Raney nickel results in good yields of ethers.[28] 3′-*O*-Benzyl-2′-deoxy-5-trifluoromethyl-β-uridine (**43**), claimed as a possible antitumor agent, has been prepared in this way (equation 39).[105]



**(43)**

(39)

Nicolaou and coworkers have not only used thioxocarboxylic esters as precursors of the first stable 1,2-dithietane,[106] but also as a photochemical approach to the oxepane system (equation 40),[106–109] which could be useful in a total synthesis of brevetoxin B.[109]

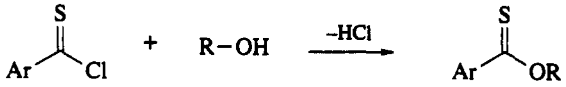


(40)

On account of the increased attention the class of thioxocarboxylic esters has recently gained, new and successful efforts have led to a considerable improvement in the methods that are available for the preparation of these compounds. The advances in this field are clearly described in several review articles and monographs which have appeared in the last decade.[6,14,15,25,28]

### 2.5.3.1 Thioacylation of Alcohols and Phenols with Thioacyl Halides

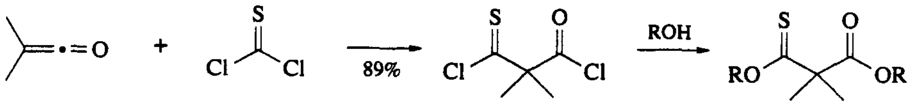
Thioacyl halides are not easily accessible. Aliphatic derivatives, in particular, can only be isolated in rare cases. Thioacylations of alcohols are therefore less important as synthetic methods than acylation of thiols with acyl halides. Nevertheless, a variety of *O*-alkyl and *O*-aryl arenecarbothioates (**2**) have been obtained according to equation (41).[6,14,25,28]



(41)

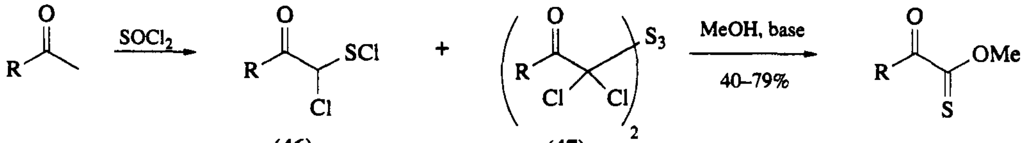
**(2)**

A stable aliphatic thioacyl chloride (**44**) was obtained according to equation (42) and used in alcoholysis reactions to prepare thioxo malonates (**45**).[110] A mixture of sulfenyl chloride (**46**) and trisulfide (**47**), which does not however contain an α-oxothioacyl chloride,[111] also yields thioxoesters on base-catalyzed reaction with methanol (equation 43).[111]



(42)

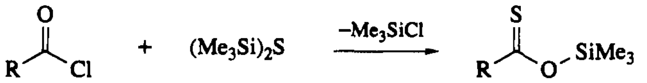
**(44)** **(45)** R = Me, Ph



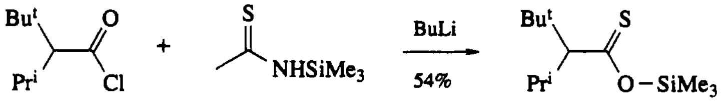
(43)

**(46)** **(47)**

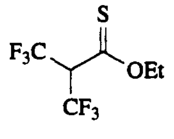
Interestingly, *O*-trimethylsilyl carbothioates are formed if acyl chlorides react with trimethylsilyl sulfides (equation 44)[14,25] or *N*-trimethylsilylthioacetamide (equation 45).[112] This is obviously due to the strong silicon–oxygen bond present in the products. *O*-Alkyl perfluoroalkanethioates, *e.g.* (**48**) and (**49**), were also obtained by alcoholysis of perfluoroalkane thiocarbonyl chlorides.[6,14,25,28]



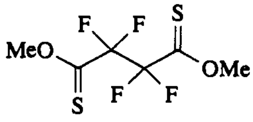
(44)



(45)



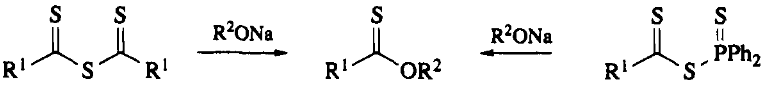
**(48)**



**(49)**

### 2.5.3.2 Thioacylation of Alcohols and Phenols with Anhydrides, Thioketenes, Thioesters and Dithioesters

The utility of various thioxo- and dithio-carboxylic anhydrides was recently reviewed by Martin and Barnikow,[113] who pointed out that bisthioacylthioanhydrides and the mixed anhydrides of dithiocarboxylic and diphenyldithiophosphinic acids are effective thioacylating agents for alcohols (equation 46), whereas carboxylic dithiocarboxylic anhydrides transfer an acyl group to a nucleophile.

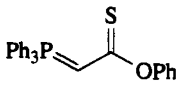


(46)

Thioketenes are stable isolable compounds only if the heterocumulene system is protected against dimerization by bulky substituents or perfluoroalkyl groups.[114] In these cases they are suitable educts for addition of hydroxylic compounds.[6,14,25,28,114,115] This reaction is also possible for the ylid (**50**). The resulting thioxoester (**51**) does not however react with *p*-nitrobenzaldehyde in a Wittig reaction.[115]

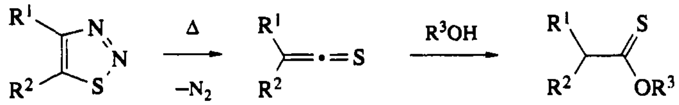
$Ph_3P{=}{\bullet}{=}{\bullet}{=}S$

**(50)**



**(51)**

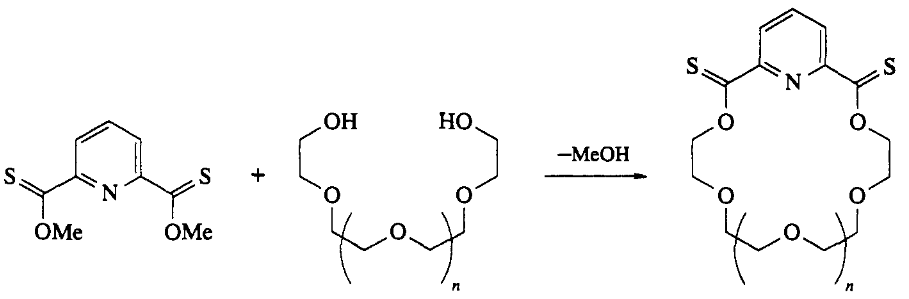
Furthermore, transient thioketenes with a wide variety of substituents R$^1$ and R$^2$, including hydrogen, can be generated by flash vacuum thermolysis of 1,2,3-thiadiazoles.[114] By *in situ* reactions thioxoesters are formed with alcohols (equation 47).



(47)

Interconversion of a thioxocarboxylic ester with an alcohol can be achieved in the presence of a base.[25,28] The reaction takes place with high yields if amino alcohols or diols are used. A series of macrocyclic polyether thioxoesters has been prepared by treating *O,O'*-diethyl dithiooxalate and *O,O'*-dimethyl 2,6-pyridinedicarbothioate with glycols. Methanol or ethanol were removed from the equilibrium mixture by distillation or adsorption in molecular sieves (equation 48).[28,116]

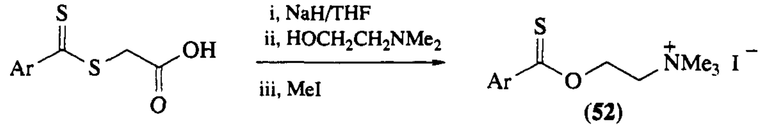
Transesterification of dithiocarboxylic esters with alcohols or alcoholates occurs in the presence of bases. In particular, the highly reactive sodium salts of methoxycarbonyl carbodithioates are used, which can be applied conveniently in aqueous solution or, if hydrolysis has to be avoided, in dry



(48)

$n =$ 2 3 4 5
yield $=$ 71 39 26 10 %

THF.[14,25,28,117,118] For instance, the thioxobenzoylcholine (**52**), which is a powerful *N*-thiobenzoylating agent itself and can be advantageously used in peptide sequence analysis, was prepared according to equation (49).[118]

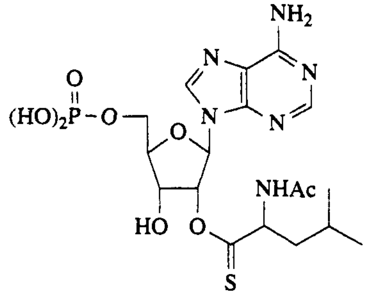


**(52)**

(49)

The above-mentioned *O*-deoxyribosyl thiobenzoate (*cf.* equation 39) was obtained from 1,5-protected deoxyribose and phenyl dithiobenzoate.[105] Also vinyl arenecarbodithioates were shown to be applicable for the synthesis of thioxoesters.[119]

The interesting *O*-alkyl ferrocenecarbothioates are available from *S*-methyl ferrocenecarbodithioate.[120] Instead of thioxo- or dithio-carboxylic esters thioacylimidazoles were successfully applied in certain cases,[6] for instance in preparing 2′- (**53**) or 3′-*O*-(*N*-acetylthioleucyl)adenosine 5′-phosphate.[121]



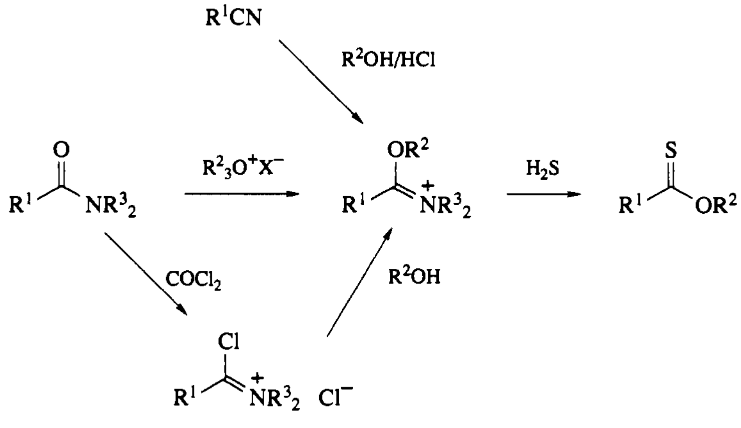
**(53)**

### 2.5.3.3 Acylation of Hydrogen Sulfide (Sulfhydrolysis) with Imidates and Orthoesters

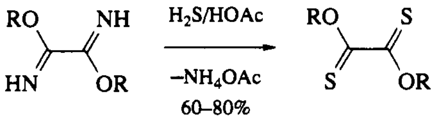
Sulfhydrolysis of imidates is one of the most powerful tools in the field of thioxoester synthesis.[6,14,15,25,28] Advantageously, hydrochlorides or acetates are used as substrates instead of the free bases. Nitriles are useful precursors, but in some cases amides or imidochlorides are preferred as the starting material, according to Scheme 5.[6,14,15,25,28]

This method can be applied with almost every substituent $R^1$ and $R^2$. Thioxoesters of dicarboxylic acids can also be prepared *via* the imidates. Fully characterized authentic compounds of this type were, however, not obtained until the 1970s. Synthetic problems arise especially if the thioxoester groups are close enough to each other to permit formation of heterocycles during their synthesis.

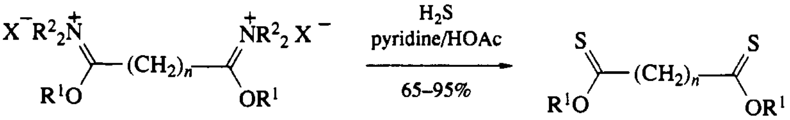
Dialkyl bisthioxooxalates are obtained if the sulfhydrolysis is performed in the presence of acetic acid (equation 50).[122,123] The method also works successfully in the case of the homologous dicarboxylic acids (equation 51),[21,124] including the unsaturated fumaric acid.[20] The preparation and further reaction of the appropriate imidates is not always straightforward. As Hartke and coworkers[20,21,124] have shown, special substituents $R^2$ at the nitrogen atoms and carefully chosen reaction conditions are required in order to get high yields and pure products.



**Scheme 5**



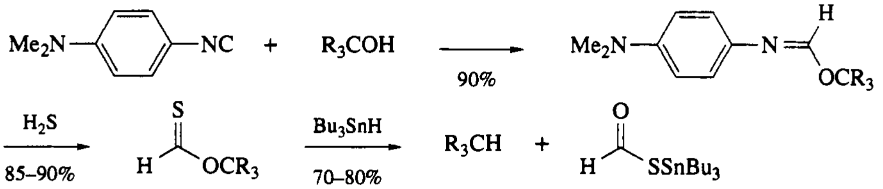
(50)



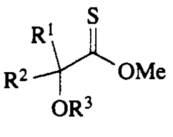
(51)

$2R^2$ = 2H, 2Me, $-(CH_2)_5-$ $n$ = 1–5; $R^1$ = Me, Et

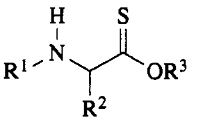
Sulfhydrolysis of imidates is also the method of choice for preparing *O*-*t*-alkyl thioformates (equation 52),[104] *O*-methyl 2-hydroxy-, 2-mesyloxy- and 2-acetoxy-thiocarboxylic esters (**54**),[125] and especially the thioxoesters of amino acids and peptides. The first examples of the latter class of compound were described by Ried and von der Emden (1960).[126] More recently the preparation as well as the biochemical behavior, the thioacylating properties in particular (*cf.* Section 2.4, this volume), have been intensely studied[126–130] and thioxoesters of amino acids with different protecting groups (**55**) have been explored. Attempts to improve the leaving properties of the alkoxy groups by introduction of a 2-nitro substituent resulted in poorer yields of thioxoesters.[127]



(52)



**(54)** $R^1$ = H, $R^2$ = Ph
$R^1$ = $R^2$ = Me
$R^3$ = H, Ms, Ts



**(55)**

t-BOC,[130] Ts,[126] Phth,[126] Fmoc[127]

A special route from imidates to *O*-ethyl arenecarbothioates *via* *O*,*N*-acetals of α-keto nitriles as intermediates is also suitable for the preparation of nitro derivatives which are difficult to obtain in good yields by other methods (equation 53).[131]

(53)

Orthoesters undergo sulfhydrolysis in the presence of proton or Lewis acids ($ZnCl_2$, $FeCl_3$).[25] This method is still the best for the preparation of *O*-ethyl thioformate.[25,132]

In a similar way to the formation of open-chain thioxocarboxylic esters, thioxolactones are obtained from cyclic imidates.[28] Kaloustian *et al.*[133] have studied this reaction and its mechanism in detail. It is closely related to the sulfhydrolysis of dialkoxycarbenium ions, which also results in the formation of thioxoesters or thioxolactones (Scheme 6).[134]

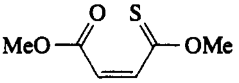
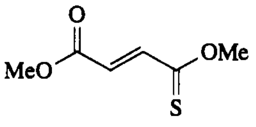
*O*,*O*-Dimethyl monothiomaleate (**56**) and monothiofumarate (**57**) are formed in a complicated reaction from 2,5-dimethoxythiophene *via* an intermediate of the orthoester type.[135] *O*-Trimethylsilyl ketene-*O*,*O*-acetals are readily formed from carboxylic esters and can be transformed to thioxoesters, without being isolated, by reaction with hydrogen sulfide, according to equation (54).[136] Methyl thioxoarachidonate (**58**) was prepared by this route.[136]



**(56)**



**(57)**

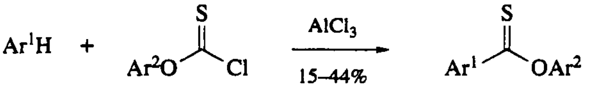
(54)

### 2.5.3.4 Thioacylation of Arenes and Carbanions under Formation of Carbon–Carbon Bonds

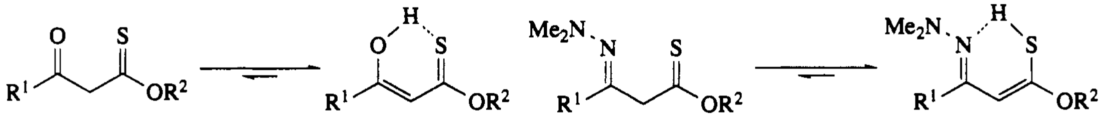
As with the thiol ester series (Section 2.5.2.5) acylation reactions of this type are treated in other parts of this work. However, the most important synthetic reactions should be mentioned here.

Friedel–Crafts thioacylation (*cf.* Volume 2, Chapter 3.1) can be performed with *O*-aryl chlorothioformates (equation 55). The yields are only moderate and no *O*-alkyl derivatives are available.[25]

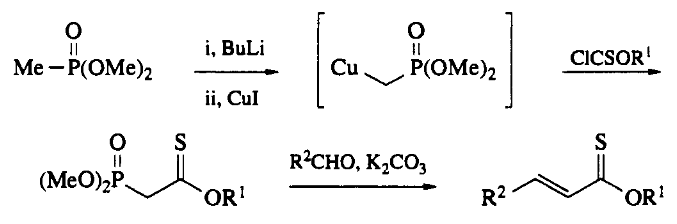


(55)

Carbanions (*cf.* Chapter 2, Chapter 3.4) derived from ketones, hydrazones or phosphonates react with *O*-alkyl chlorothioformates or thiocarbonates, resulting in *O*-alkyl β-oxo- (**59**),[137] β-hydrazono- (**60**)[138] or α,β-unsaturated-carbothioates (equation 56).[139]



**(59)** **(60)**



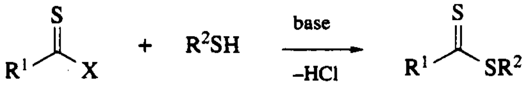
(56)

## 2.5.4 DITHIOCARBOXYLIC ESTERS AND DITHIOLACTONES

Although, presumably, dithiocarboxylic esters are prepared by alkylation of the strongly nucleophilic dithiocarboxylate salts in most cases (Section 2.5.1), thioacylation procedures provide a valuable alternative.[6,14,15,26,27,29,140,141] In particular, the sulfhydrolysis of imidothioates (Section 2.5.4.3) has retained its importance due to the convenient availability of the starting material, a nitrile or thioamide.

### 2.5.4.1 Thioacylation of Thiols with Thioacyl Halides, Thioacyl Anhydrides and Thioketenes

Thioacyl halides react with thiols in the presence of base and high yields of alkyl or aryl dithiocarboxylates (**3**) are obtained according to equation (57).[26]



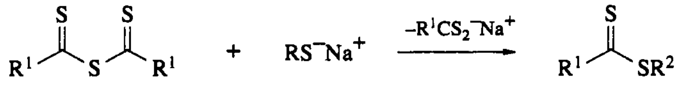
(57)

**(3)**

Thiols can also be thioacylated, in the same way as alcohols (Section 2.5.3.2),[113] by reaction with bisthioacyl thioanhydrides (equation 58). The preparation of aromatic as well as aliphatic thioanhydrides is possible according to novel procedures described by Kato *et al.*,[142–144] *e.g.* from the corresponding dithiocarboxylic acids and DCC[142] or 2-chloro-*N*-methylpyridinium iodide.[143] Even sterically hindered dithioesters are obtained (equation 58).[144]

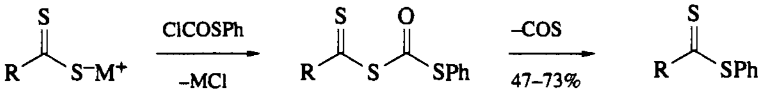
Phenyl carbodithioates are obtained in acceptable yields by an intramolecular thioacylation according to equation (59).[145] The intermediate mixed thiocarboxylic thiocarbonic acid anhydride is not isolated but spontaneously eliminates carbon oxysulfide.

Thioacyl diphenylthiophosphinyl sulfides are useful thioacylating reagents too, which give dithioesters in good yields under mild reaction conditions (equation 60).[146]

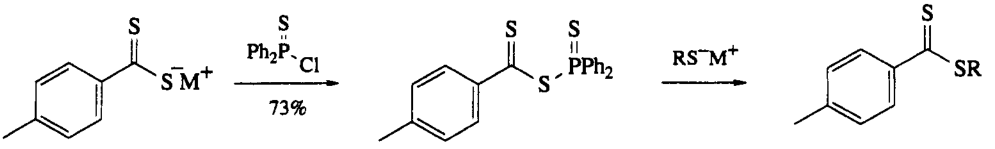


(58)

(3) $R^1 = Pr^i$, $R^2 = Bu^t$; 20%



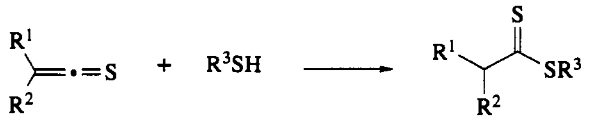
(59)



(60)

R = Et, M = Li; 74%
R = Ph, M = Na; 90%

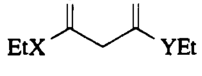
Stable, as well as transient, thioketenes give dithiocarboxylic esters on reaction with thiols (equation 61).[114]



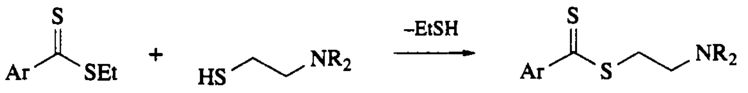
(61)

### 2.5.4.2 Transesterification of Thiols

The interchange reaction between a thioxoester and a thiol does not, in general, represent a meaningful synthetic procedure since dithioesters are more readily available than thioxoesters in most cases. However, *O*,*S*-diethyl trithiomalonate (**61b**) and diethyl tetrathiomalonate (**61c**) were prepared from *O*,*O*-diethyl dithiomalonate (**61a**).[21] On the other hand, the transformation of one dithiocarboxylic ester into another can be a useful and practicable reaction. For instance, ethyl arenecarbodithioates are interconverted to 2-dialkylaminoethyl arenecarbodithioates,[14] according to equation (62).

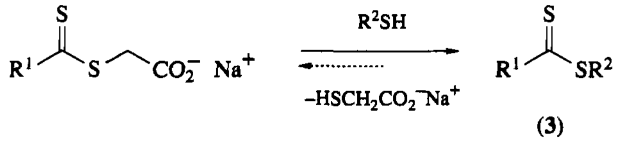


(**61a**) X = Y = O
(**61b**) X = O, Y = S
(**61c**) X = Y = S



(62)

The highly activated sodium salts of carboxymethyl carbodithioates, which can be easily obtained by alkylation of sodium carbodithioates with bromoacetic acid,[14,147,148] have especially found application for the thioacylation of thiols.[6,14] Since the products are insoluble in water, the equilibrium reaction (equation 63) is shifted to the product side. Also vinyl arenecarbodithioates are reactive enough to be interconverted with potassium alkanethiolates.[119]

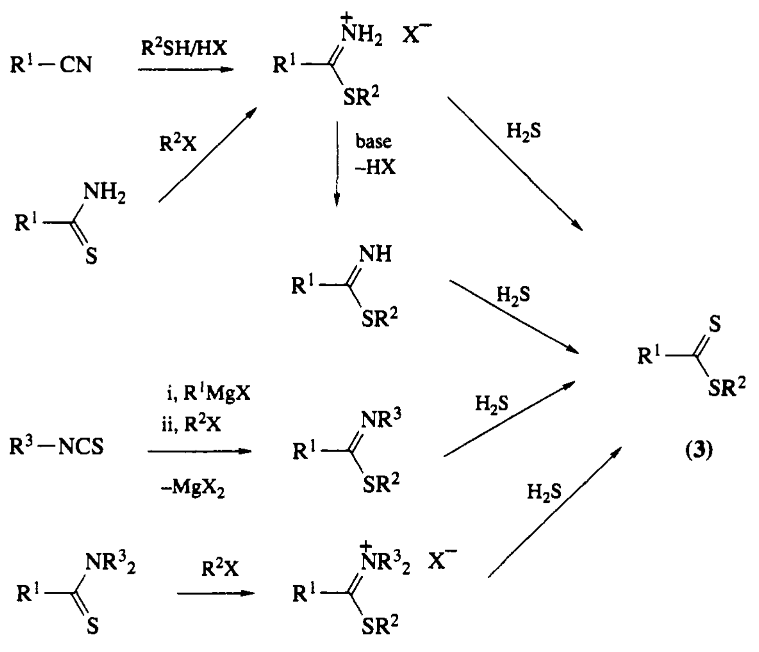


(63)

The unnatural coenzyme A dithioesters were synthesized by transesterification and their reactions with enzymes (acetyl transferase) studied.[149]

### 2.5.4.3 Acylation of Hydrogen Sulfide (Sulfhydrolysis) with Imidothioates and Related Compounds

Imidothioates in the neutral or ionic form are the most generally applied educts for the preparation of dithiocarboxylic esters. They are themselves prepared from nitriles, thioamides or isothiocyanates, and react with hydrogen sulfide under appropriate conditions to yield the dithioesters (Scheme 7).[6,14,26,27,29,141] Interesting examples (**62**)–(**73**) were described in the recent literature.



Scheme 7

Nitriles can be used as starting material for the bisdithioesters (**62**; $n = 4, 5, 10$),[124,150] whereas the derivatives with shorter chain lengths (**62**; $n = 1–3$),[21,124] as well as methyl dithiocinnamate (**63**),[20] are accessible from *N,N*-disubstituted thioamides *via* the corresponding imidothioate iodides. Methyl dithioacrylate (**65**), the simplest unsaturated dithioester, was prepared by flash vacuum thermolysis of a precursor dithioester (**64**), which had been obtained from the corresponding nitrile (equation 64).[151] It can be isolated as a red monomeric compound at 77 K but dimerizes rapidly at room temperature. The $\beta,\gamma$-unsaturated isoprene derivative (**66**)[152] and the methyl 2-arylpropanedithioates (**67**)[141] were prepared from phenyl isothiocyanate and used as educts for syntheses of lavandulal and *ar*-curcumene. Also ethyl furane-3-carbodithioate (**68**), as prepared from the nitrile, has found application in syntheses of the natural products egona ketone and *ar*-turmerone.[141]

Markedly branched alkyl 3,3,3-trialkylpropanedithioates (**69**) can be prepared by 1,4-addition of organometallics to $\alpha,\beta$-unsaturated imidothioates and subsequent sulfhydrolysis of the ketene *S,N*-acetals according to equation (65).[141,153]

Dithioesters of various amino acids with different *N*-protecting groups have been prepared. The corresponding nitriles are suitable educts in many cases (**70**).[154,155] Using $^{13}C$ sodium cyanide or $^{15}N$ ammonium chloride as starting material, Storer *et al.*[154] were able to prepare the respective isotopically labeled

amino acid dithioesters, model compounds for studies on enzyme–substrate complexes. However, *N*-*t*-butyloxycarbonyl derivatives (**71**)[130] cannot be obtained in this way, since obviously deprotection occurs under the strongly acidic conditions of the first step. Instead, amino acid thiopiperidides have been successfully used.[130] Levesques *et al.* have prepared polydithioesters of type (**72**) from polyacrylonitrile[156] and (**73**) from polyethylene oxide *via* the polythioamide.[157]

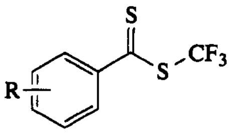
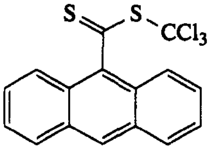
### 2.5.4.4 Dithiocarboxylation of Arenes and Carbanions under Formation of Carbon–Carbon Bonds

As in previous sections of this chapter, only short comments will be made on this type of thioacylation. Reaction of benzene and activated arenes with alkyl or aryl chlorodithioformates under Friedel–Crafts conditions or with (alkylthio)thiocarbonyl hexafluoroantimonates, $(RSC{=}S)^+\ SbF_6^-$,[158] results in formation of the corresponding arenecarbodithioates.[6,14,26,27,156] Three interesting new examples, (**74**),[159] (**75**)[160] and (**76**),[156] may illustrate the scope of the reaction.

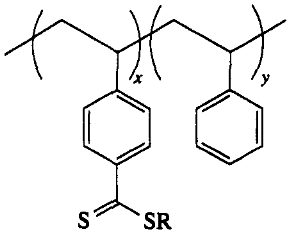
Methyl chlorodithioformate has also been used to prepare the methyl cyclopropanecarbodithioate (**77**; equation 66),[161] whereas dimethyl trithiocarbonate was reacted with the carbanions of ketones[162] and



**(74)** R = H, F, $CF_3$, OMe



**(75)**



**(76)**

other compounds with activated methyl or methylene groups[163] to yield, for example, the methyl carbodithioates **(78)**[162] and **(79)**.[163]

## 2.6.1 INTRODUCTION

As well as thiol esters, selenol esters (**1**) frequently exhibit a high and selective reactivity toward nucleophiles, which is enhanced even further by activation with heavy ions or oxidizing agents. These properties make selenol esters valuable acyl transfer agents. This review deals with general methods for the synthesis of selenol esters and their reactivity as acyl transfer agents. Furthermore, selenoesters (**2**), isomeric compounds of selenol esters, and their derivatives selenoamides (**3**) are also described. These compounds show the characteristic reactivity based on the carbon–selenium double bond.

Hitherto known reviews for the chemistry of selenol esters and their derivatives are shown in refs. 1–5.

## 2.6.2 SELENOL ESTERS

### 2.6.2.1 Preparation

Many methods for the preparation of selenol esters have been developed. These can be classified into the following five general methods according to the types of reaction.

#### *2.6.2.1.1 Acylation of selenols and their metal salts*

In 1962 Renson *et al.* reported that a variety of selenol esters can be synthesized by the reaction of the appropriate acyl chlorides with selenols in the presence of pyridine.[6,7] Selenols can easily be prepared from elemental selenium and the corresponding Grignard reagents. In addition to simple selenol esters, α,β-unsaturated selenol esters (**4**) and (**5**) and *o*-substituted aromatic selenol esters (**6**) have been obtained by this method, as shown in Scheme 1. Butyl selenol esters are generally colorless or light yellow liquids, whereas the phenyl or substituted phenyl selenol esters are white solids, which are easily purified by recrystallization. More recently other groups have used Renson's method to synthesize similar selenol esters.[8–10]

**Scheme 1**

It has been reported that some selenols are directly acylated by carboxylic acids to give selenol esters.[11–14] For example, heating of 4-hydroselenobutyric acid at about 160 °C resulted in ring closure to give the corresponding γ-lactone (equation 1).[11]

 (1)

Areneselenyl magnesium bromide has been reported to react with *p*-substituted benzoyl halides, giving aromatic selenol esters[15–17] as the first examples exhibiting liquid crystal properties (equation 2).[15]

 (2)

Alkali metal salts of selenol can also be used in the synthesis of selenol esters.[17–22] Axial and equatorial selenol esters of cholestane and androstanone have been prepared from the potassium salt (**7**) and benzoyl chloride (Scheme 2 illustrates the axial isomer).[18]

(3)

Tetraethylammonium borohydride reduces diphenyl diselenide to phenylselenolate anion. When an acyl halide is added to the toluene solution of phenylselenolate anion, the corresponding acylation product is isolated in good yield (equation 4).[24] Resin-supported phenyl selenide anion underwent acylation with acetyl chloride under mild reaction conditions.[25]

(5)

A mild and convenient method has been attained by using the imidazolide (**8**; equation 6) or triazolide (**9**; equation 7) of carboxylic acids as a key intermediate. Treatment of an imidazolide of carboxylic acid with 1.2 equiv. of benzeneselenol and 0.02 equiv. of sodium phenoxide provided the selenol ester in a quantitative yield.[27] In the case of the triazolide of carboxylic acids, the reaction proceeded in the absence of base.[28]

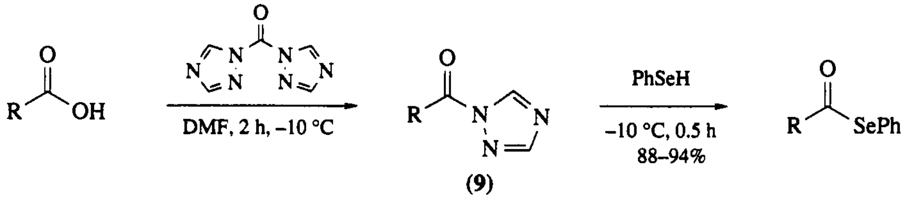
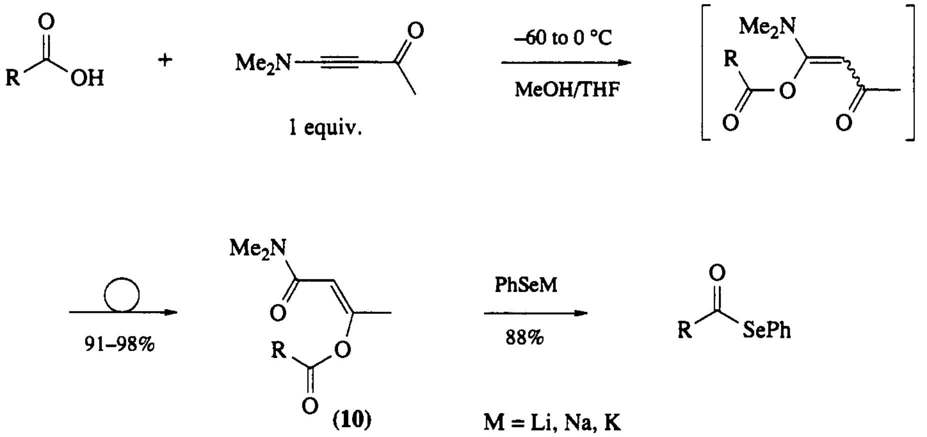
(6)

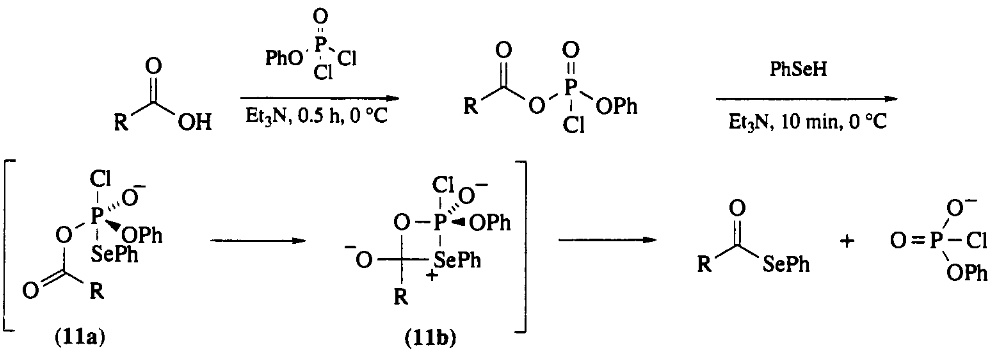


Reaction of some vinyl esters (**10**; Scheme 3) of carboxylic acids with selenolate gave the corresponding selenol esters in high yields because of the good leaving ability of enolate.[29]



Scheme 3

Reaction of carboxylic acids with phenyl dichlorophosphate, followed by the addition of benzeneselenol to the mixture afforded selenol esters (Scheme 4).[30] The reaction is assumed to proceed *via* the pentacovalent oxyphosphorane intermediates (**11a**) and (**11b**).



Scheme 4

It has recently been disclosed that the electrophilic cleavage of zirconocene complex (**12**; Scheme 5) leads easily to new *Se,Se′*-disubstituted derivatives of benzene-1,2-diselenol (**13**) in good yields, with quantitative recovery of the organometallic moiety of the reagent.[31,32]

### *2.6.2.1.2 Alkylation of selenocarboxylates*

As well as acylation of selenols, alkylation of selenocarboxylates with alkyl halides is one of the most straightforward methods for synthesis of selenol esters. However, known examples of selenol esters synthesized using this strategy have been limited to a few cases,[33–37] due to the difficulty of the preparation of selenocarboxylates.

Jensen *et al.* reported that selenobenzoic *Se*-acid (**14**; equation 8) is formed as the primary product of the reaction of benzoyl chloride with hydrogen selenide in pyridine, but (**14**) is a very unstable liquid that reversibly loses hydrogen selenide to give dibenzoyl selenide. On rapid treatment with *p*-nitrobenzyl bromide, the selenobenzoic *Se*-acid formed *in situ* produced (*p*-nitrobenzyl)selenobenzoate in high yield.[33]

### *2.6.2.1.3 Reaction of esters with aluminum selenolate*

One of the most general methods for synthesis of selenol esters uses dimethylaluminum methylselenolate (**16**), which has been found to be a remarkably efficient and versatile reagent for the conversion of *O*-alkyl esters to their corresponding methylselenol esters under mild conditions.[38,39] The reagent (**16**) is conveniently prepared by heating a toluene solution of trimethylaluminum with powdered selenium for 2 h under reflux. The transformation of various esters to selenol esters can be completed within 1 h. Representative results are shown in Scheme 6 (**17–23**). This method can also be applied to cyclic esters (**19**) and esters (**20**)–(**23**) containing other functional groups.

Reaction of methyl *trans*-4-*t*-butylcyclohexanecarboxylate (**24b**; equation 12) with (**16**) proceeded much faster than the reaction of the *cis* isomer (**24a**; equation 11), a result suggesting that this method is highly sensitive to steric factors.[40–42]

### *2.6.2.1.4 Reaction of carboxylic acids with selenocyanates or* N*-PSP in the presence of trialkylphosphine*

It has been reported that aryl selenocyanate (**25**; Scheme 7) reacts with carboxylic acids in the presence of tributylphosphine under mild conditions, giving rise to selenol esters in good yields.[43] The process may involve the reaction of carboxylic acids with selenophosphonium salt (**26**), which is the key intermediate.

Since phenyl selenocyanate (**25**; Ar = Ph) is a sensitive liquid, which slowly decomposes on storage during a few days, an improved method using *N*-phenylselenophthalimide (*N*-PSP; **27**), a stable crystalline compound, has been developed.[44,45] In general, the yields of selenol esters prepared from *N*-PSP/$Bu_3P$ are higher than those obtained employing ArSeCN/$Bu_3P$.

*N*-Acetylselenenamide (**28**) can also be used in place of (**25**) or (**27**).[46]

### *2.6.2.1.5 Miscellaneous*

The reaction of *N*-acylhydrazines with benzeneseleninic acid (**29**; Scheme 9) in the presence of triphenylphosphine afforded high yields of diverse selenol esters.[47–49] Alkyl, cycloalkyl and aryl selenol esters were prepared, even in the case of the highly hindered compounds (**30**) and (**31**).

The removal of sulfur and selenium atoms from compounds (**32**) and (**33**) using triphenylphosphine easily furnished the corresponding selenol esters (equation 13).[50,51]

Diaryl diselenides reacted with carbon monoxide (5–100 atm) at 100–200 °C, in the presence of $Co_2(CO)_8$ as a catalyst, to give the corresponding selenol esters of aromatic carboxylic acids in 21–96% yields (equation 14).[52]

### 2.6.2.2 Reactions

Selenol esters are expected to be a more reactive species than the corresponding thiol esters or oxo esters due to the comparatively weak bonding between carbon and selenium. The ability of the selenol esters to serve as active acyl transfer agents has been readily demonstrated by the easy conversion of the selenol ester (**34**; equation 15) to its corresponding acid (**35**), ester (**36**) or amide (**37**).[38,53] This acyl–selenium bond cleavage has also been promoted by $\mathrm{Cu^I}$ and $\mathrm{Cu^{II}}$ salts.[38,39] The isopropylidene derivative (**38**; equation 16) of ribofuranosylacetate has been converted to a lactone (**40**) in good yield *via* the selenol ester (**39**).

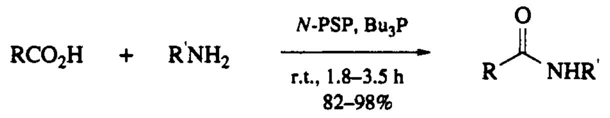
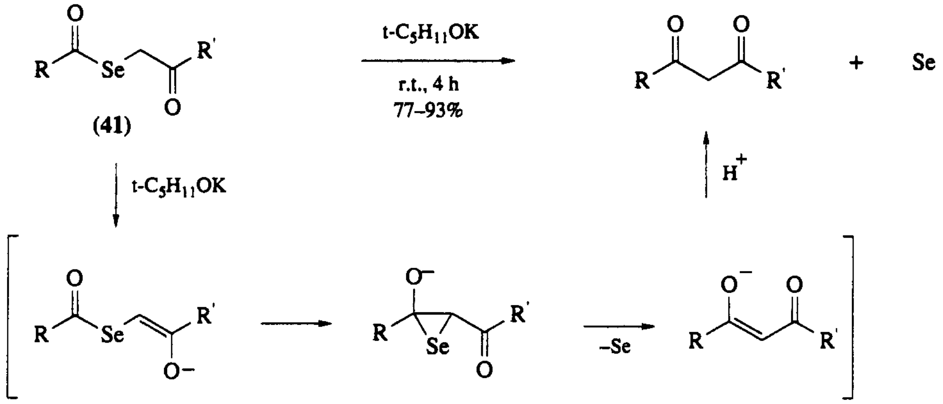
Single-step conversion of carboxylic acids to amides has been achieved using the *N*-PSP/$Bu_3P$ reaction system in the presence of amines (equation 17).[44,45]



$$RCO_2H + R'NH_2 \xrightarrow[\text{r.t., 1.8–3.5 h}]{N\text{-PSP, }Bu_3P} RC(O)NHR' \qquad (17)$$

82–98%

Some examples of carbon–carbon bond formation by the reaction of selenol esters with carbon nucleophiles have been reported. *Se*-Acylmethyl selenocarboxylates (**41**) readily extruded selenium by treatment with potassium *t*-pentoxide to form 1,3-diketones in good yields.[35] A proposed pathway is outlined in Scheme 10.



**(41)**

**Scheme 10**

A mild and efficient transformation of esters into ketones *via* selenol esters has been developed. Selenol esters smoothly reacted with organocuprates to produce ketones in excellent yields (equation 18).[40] Reaction with a vinylcopper(I) reagent gave α,β-unsaturated ketones (equation 19).[54] Butylmanganese chloride also transformed selenol esters into ketones, although 3 equiv. of the reagent are required to complete the reaction. $Me_2Cd$ and PhHgBr were not effective for this transformation.

The copper or copper(I) iodide-catalyzed insertion of diazomethane into the acyl–selenium linkage of selenol esters was reported to afford the corresponding ketones as the chief products.[55,56] A nonconcerted mechanism involving a tetrahedral intermediate (**42**; Scheme 11) has been suggested.

Moreover, the selenol esters can acylate reactive arenes and heteroaromatic compounds when copper(I) triflate is employed as the selenophilic metal cation.[39,57] The acylation of aromatics by use of the benzene complex of copper(I) triflate (**43**; Scheme 12) was complete within an hour at room temperature, with benzene as solvent, and the acylation products were obtained in high yields. Intramolecular acylation was examined successfully, as shown in equation (20).

Selenol esters also reacted with isonitrile (**44**; Scheme 13) at room temperature for 6–20 h in the presence of 1.5 equiv. of copper(I) oxide and triethylamine (or DBU) to give oxazole (**45**).[39,57] The reaction presumably proceeds through an intermediate β-ketoisonitrile (**46**), and copper(I) oxide functions as a reagent for complexation to the selenium moiety.

Recently it has become apparent that phenyl selenides (**47**; Scheme 14) are efficiently reduced to alkanes (**48**) with tin hydride by a free radical process.[58]

The reaction of selenol esters with tributyltin hydride resulted in the formation of the corresponding aldehydes (**49**) and alkanes (**50**).[59,60] The formation ratio of aldehydes to alkanes depends on the reaction temperature, as exemplified in Scheme 15. When the reaction was carried out with UV irradiation at ambient temperature, the aldehyde was formed predominantly, in high yields.

A new method for the transformation of —$CO_2H$ to —H has been attained by formation of the selenol ester from carboxylic acid, followed by its reduction.[59–64] Owing to high chemoselectivity and mild reaction conditions, this method is often utilized for the synthesis of natural products (equation 21).[30]

## 2.6.3 SELENOESTERS

### 2.6.3.1 Preparation

In an earlier investigation, aryl selenoesters have been prepared by the reaction of hydrogen selenide with imido esters (**56**; equation 24), but the yields were very low (**56**; R = Ph, 5.6%; **56**; R = *p*-tol 3%).[69,70] The yield was somewhat improved by employing methyl benzimidate hydrochloride (**57**; equation 23) as the starting material.[71]

A practically useful method for synthesis of selenoesters has been developed by Barton *et al.* A wide range of aliphatic and aromatic selenoesters have been synthesized from the appropriate *N*,*N*-disubstituted imidoyl chlorides (**58**) using sodium hydrogen selenide to introduce selenium.[72,73] Imidoyl chlorides (**58**) can be obtained by the reaction of amides with phosgene. Representative results are shown in Scheme 17 (formulae **59**–**61**).

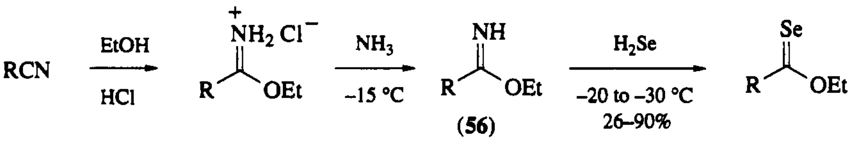
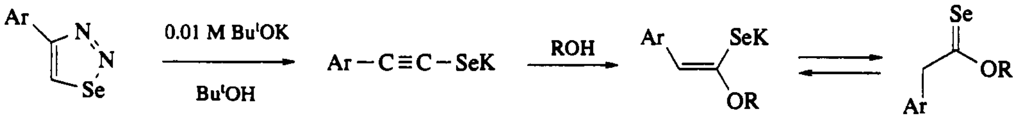
**Scheme 17**

Cohen investigated in detail the addition of hydrogen selenide to imido esters (**56**), and found that selenoesters can be prepared by the reaction at –20 to –30 °C in the presence of pyridine–triethylamine.[74]



(**56**) (24)

α-Substituted selenoesters (**64**) have been synthesized by the reaction of alcohols with arylethynylselenolate salts (**63**), prepared from 4-aryl-1,2,3-selenadiazoles (**62**).[75]



(**62**) (**63**) (**64**)

**Scheme 18**

The transition metal complex pentacarbonyl(methoxyarylcarbene)chromium(0) (**65**), gave selenoesters on treatment with elemental selenium.[76]

Although alkylation of potassium selenobenzoate with alkyl halides led to the formation of selenol esters *via Se*-alkylation, as described in Section 2.6.2.1.1 (equation 9), the reaction of (**66**; equation 26) with trimethylsilyl chloride proceeded through *O*-silylation to give trimethylsilyl selenobenzoate (**67**) in 68% yield.[77] The driving force of the reaction may be due to the strong affinity of silicon for oxygen.

The aliphatic selenoesters are generally yellow liquids, while the aromatic esters are deep red oils, the latter being more stable. However, after 2–3 days, these begin to decompose slowly, accompanied by the deposition of elemental selenium, although they can be stored in a refrigerator for a few months without any such precipitation.[74]

### 2.6.3.2 Reactions

Owing to the high polarizability of the carbon–selenium double bond, selenoesters can easily be attacked by nucleophiles. This property makes a selenoester a useful reagent for the synthesis of heterocycles.[78–83] Condensation of selenoesters with bifunctional aromatic or aliphatic amines has yielded a variety of nitrogen-containing heterocyclic compounds (Scheme 19).

Selenazofurin (**72**), a promising antitumor agent, has been synthesized from methyl 2,5-anhydroallonimidate (**68**), as illustrated in Scheme 20. The key step of the synthesis is the formation of the selenazole (**71**) by the condensation of the selenoester (**69**) with ethyl 2-amino-2-cyanoacetate (**70**).[83]

In order to clarify the fundamental chemical reactivity of selenoesters, Barton *et al.* investigated their reaction behavior towards a number of common reagents.[72] The reduction of selenoesters was examined using sodium borohydride–triphenylphosphine or Raney nickel (W-2). In both cases, the corresponding ether (**73**) was obtained in high yield. On the other hand, selenoesters were converted into their parent oxocarbonyl derivatives (**76**) in high yield on treatment with oxidizing agents such as benzeneseleninic anhydride (**74**)[84,85] and bis(*p*-methoxyphenyl) telluroxide (**75**; Scheme 21).[86]

The reaction of a selenoester with the methylene Wittig reagent (**77**) readily produces the vinyl ether (**78**; equation 27).[72]

During these investigations, it was observed that the selenoester reacts with triphenylphosphine in the presence of atmospheric oxygen to give the parent ester.[72] Hansen investigated in detail the reactions between triethylphosphine and a number of aliphatic and aromatic selenoesters.[87] Under oxygen-free conditions, the reaction of aliphatic selenoesters with triethylphosphine gave a purple intermediate, which was quenched with atmospheric oxygen to give the corresponding esters (**79**). In the case of aromatic selenoesters, the same reaction under oxygen-free conditions led to deselenative coupling to afford α-dialkoxy-stilbenes (**80**) and -dibenzyls (**81**). When the reaction was carried out in cyclohexene, 7-alkoxy-7-phenylbicyclo[4.1.0]heptanes (**82**) were formed. These results suggest the formation of α-alkoxycarbene (**84**). The presence of benzaldehyde in the reaction mixture led to α-alkoxystilbenes (**83**; Scheme 22).

Recently, the synthesis of selenoaldehyde was examined by the reaction of *O*-alkyl selenoformates (**85**) with aryllithium.[88–90] 2,4,6-Tri-*t*-butylphenyllithium reacted with selenoformates (**85**) at three different sites, *i.e.* the selenoformyl carbon, the selenoformyl hydrogen and the selenium, to give several reaction products including 6,8-di-*t*-butyl-3,4-dihydro-4,4-dimethyl-1*H*-2-benzoselenin (**86**). The formation of (**86**) is explained in terms of the intermediacy of 2,4,6-tri-*t*-butylselenobenzaldehyde (**87**; Scheme 23).

Selenoesters have easily undergone exchange reactions with sulfur to give the corresponding thioesters (**88**), on heating with elemental sulfur (equation 28).[91,92]

Some other reactions concerning selenoesters are shown in refs. 93 and 94.

## 2.6.4 SELENOAMIDES

### 2.6.4.1 Preparation

#### *2.6.4.1.1* N-*Unsubstituted selenoamides*

In general, *N*-unsubstituted selenoamides have been prepared by the addition of hydrogen selenide to the corresponding nitriles in the presence of base.

In an earlier investigation of the synthesis of aromatic selenoamides, gaseous hydrogen selenide was directly introduced into the reaction vessel. The first report[95] described the synthesis of benzeneselenoamide by the reaction of benzonitrile with hydrogen selenide in ethanolic ammonia (equation 29), while its 4-methyl derivative was synthesized under similar conditions.[96]

(29)

In order to avoid the handling of poisonous hydrogen selenide, two other useful syntheses have been devised. One method[97] uses the reaction of aromatic nitriles with aluminum selenide in the presence of pyridine, triethylamine and water (Scheme 24), while the other[98] is performed by the reaction of nitriles with selenium, carbon monoxide and water in the presence of triethylamine (Scheme 25). These methods are exceedingly convenient in terms of manipulation without the isolation of hydrogen selenide for the preparation of selenoamides. Using these methods, a variety of aromatic and heterocyclic selenoamides can be obtained from the corresponding nitriles in high yields.

The aromatic selenoamides are generally yellow solids and are stable enough under nitrogen at ordinary temperature to be kept for several weeks in high purity. On exposure to air, they gradually decompose into the starting nitriles, elemental selenium and water, at room temperature or below. These observations suggest that the selenoamides are in equilibrium with the corresponding nitriles and hydrogen selenide (equation 30).[98]

(30)

In contrast to aromatic selenoamides, little is known about the isolation of *N*-unsubstituted aliphatic selenoamides, which lack the stabilizing conjugation between the aromatic ring and the selenocarbonyl group. Hitherto known procedures are Kindler's method,[99–101] using the reaction of nitriles with hydrogen selenide in the presence of sodium ethoxide (equation 31), and the method using nitriles and Se–CO–$H_2O$ (Scheme 25).

Treatment of 2,3,5-tri-*O*-benzoyl-β-D-ribofuranosyl-1-carbonitrile (**89**) with liquid hydrogen selenide, with 4-(dimethylamino)pyridine as the catalyst, provided 2,5-anhydro-3,4,6-tri-*O*-benzoyl-D-allonselenoamide (**90**). Compound (**90**) was treated with ethyl bromopyruvate to provide ethyl 2-(2,3,5-tri-*O*-ben-

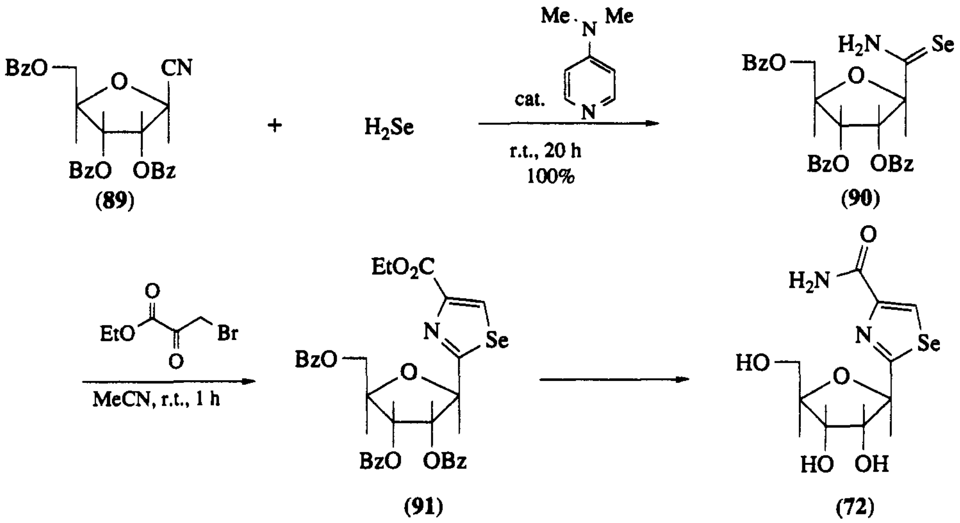
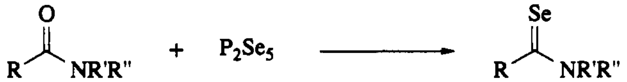
zoyl-D-ribofuranosyl)selenazole-4-carboxylate (**91**), followed by ammonolysis to give 2-β-D-ribofuranosylselenazole-4-carboxamide (**72**) as a promising antitumor agent.[102]



**Scheme 26**

### 2.6.4.1.2 *N-Substituted selenoamides*

*N*-substituted aliphatic selenoamides have been obtained on treatment of the corresponding amides with phosphorus pentaselenide in refluxing benzene,[101,103] but the yields were generally low (equation 32). Aromatic selenoamides can be obtained in moderate to high yields by the same method.[104] Improved yields of unhindered aliphatic selenoamides were obtained by heating the analogous amides with phosphorus pentaselenide in the presence of barium carbonate in boiling xylene.[105] Synthesis of selenolactams ($n$ = 3–5, 7 and 11) was accomplished by heating a mixture of the lactam with red phosphorus and gray selenium in refluxing xylene for 24 h.[106]



$$\mathrm{RC(=O)NR'R''} + \mathrm{P_2Se_5} \longrightarrow \mathrm{RC(=Se)NR'R''} \qquad (32)$$

R' = alkyl; R'' = alkyl or H

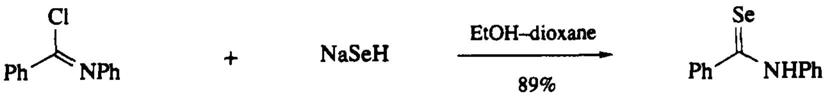
| 104 | Aryl | Pyridine reflux | None | 52–82% |
| 105 | Alkyl | Xylene reflux | $BaCO_3$ | <61% |

The reaction of an imidoyl chloride with sodium hydrogen selenide gave high yield of the selenoamide (equation 33).[107]



$$\mathrm{PhC(Cl)=NPh} + \mathrm{NaSeH} \xrightarrow[89\%]{\text{EtOH–dioxane}} \mathrm{PhC(=Se)NHPh} \qquad (33)$$

Convenient one-pot syntheses of *N*-substituted selenoamides from nitriles, metallic selenium, carbon monoxide, water and amines have been developed on the basis of an amino group exchange reaction between the *N*-unsubstituted selenoamides formed *in situ* and the primary or secondary amines.[108] Aromatic or aliphatic, and *N*-mono- or *N*,*N*-di-substituted selenoamides can be obtained in good yields by this method (Scheme 27).

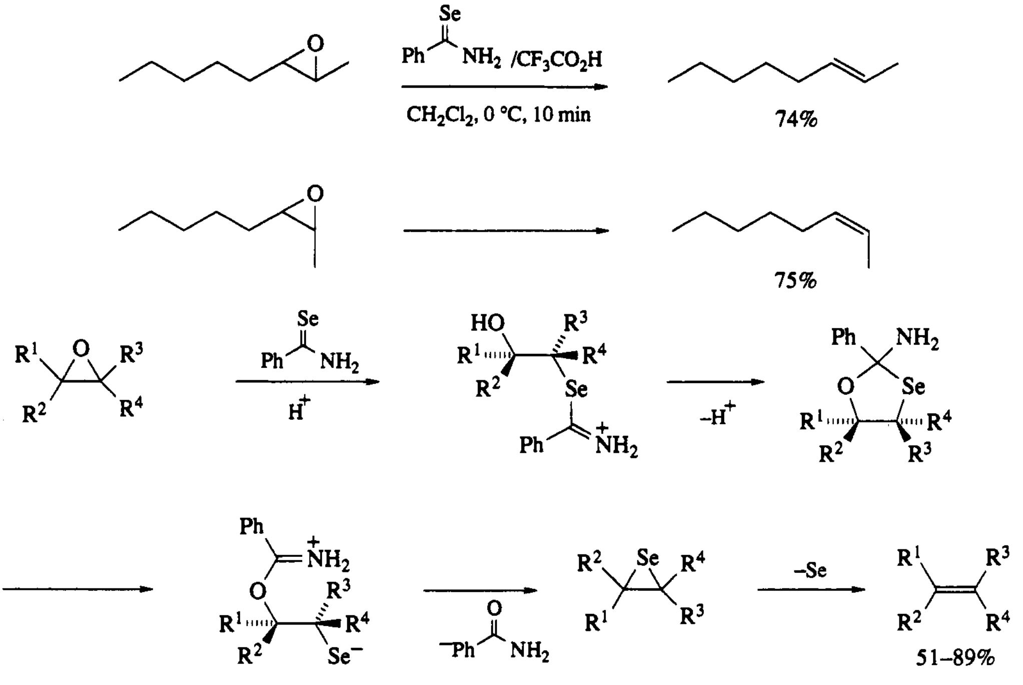
It has recently been reported that selenoamide is a useful reagent for the stereospecific deoxygenation of epoxides under mild conditions.[123] This deoxygenation can be applied to various epoxides, *i.e.* mono-, di- and tri-substituted epoxides and cyclic epoxides. A suggested reaction path is illustrated in Scheme 34.



Scheme 34

Some other reactions are shown in refs. 91, 124 and 125.

# 2.7

# Synthesis of Iminium Salts, Orthoesters and Related Compounds

WILLI KANTLEHNER
*Universität Stuttgart, Germany*

---

2.7.1 INTRODUCTION AND SCOPE 487

2.7.2 SALT-LIKE COMPOUNDS (IMINIUM SALTS) 487

*2.7.2.1 Adducts from Amides (Thioamides) and Acylating Reagents* 487
  *2.7.2.1.1 Phosphorus oxychloride and phosphorsulfur trichloride* 487
  *2.7.2.1.2 Adducts from acid amides and sulfur compounds* 490
  *2.7.2.1.3 Adducts from amides and carbonic acid derivatives* 491
  *2.7.2.1.4 Adducts from acid amides and carboxylic acid derivatives* 493
*2.7.2.2 Halomethyleneiminium Salts (Amide Halides)* 495
  *2.7.2.2.1 From halogenating reagents and acid amides* 495
  *2.7.2.2.2 By addition reactions* 497
  *2.7.2.2.3 From dihalomethyleneiminium salts (phosgene iminium salts, PI salts)* 498
  *2.7.2.2.4 From halomethyleneiminium salts* 499
*2.7.2.3 Alkoxymethyleneiminium Salts* 501
  *2.7.2.3.1 From amides and alkylating reagents* 501
  *2.7.2.3.2 From carboxylic acid amides and acylating reagents* 504
  *2.7.2.3.3 By alkylation or acylation of imino esters* 504
  *2.7.2.3.4 From halomethyleneiminium salts and related compounds* 505
  *2.7.2.3.5 From orthoamide derivatives and related compounds* 506
  *2.7.2.3.6 From carboxonium salts* 507
  *2.7.2.3.7 From nitriles or nitrilium salts* 507
  *2.7.2.3.8 Miscellaneous methods* 507
*2.7.2.4 Alkylmercaptomethyleneiminium Salts* 508
  *2.7.2.4.1 From thioamides and alkylating reagents* 508
  *2.7.2.4.2 From thioamides and acylating reagents* 508
  *2.7.2.4.3 From thioimido esters by alkylation or acylation* 510
  *2.7.2.4.4 From other methyleneiminium salts* 511
  *2.7.2.4.5 By addition of SH group containing compounds to nitriles* 511
  *2.7.2.4.6 By rearrangement of thioamides* 511
  *2.7.2.4.7 From orthoamide derivatives and related compounds* 511
  *2.7.2.4.8 From orthocarbonic acid derivatives* 512
  *2.7.2.4.9 Miscellaneous methods* 512
*2.7.2.5 Amidinium Salts (Aminomethyleneiminium Salts)* 512
  *2.7.2.5.1 From amide–acylating reagent adducts and amines or amine derivatives* 512
  *2.7.2.5.2 From carboxylic acids, amines and various condensing agents* 513
  *2.7.2.5.3 From iminium salts* 514
  *2.7.2.5.4 From imidoyl compounds* 515
  *2.7.2.5.5 From nitriles or nitrilium salts* 516
  *2.7.2.5.6 From isonitriles* 517
  *2.7.2.5.7 From thioamides, thioxoesters, thioureas, amides and various reagents* 517
  *2.7.2.5.8 From orthoesters, orthoamide derivatives and related compounds* 518
  *2.7.2.5.9 From halogen compounds* 521
  *2.7.2.5.10 Vinylogous and azavinylogous amidinium salts* 522

*2.7.2.5.11 Miscellaneous methods* 523

2.7.3 IMIDOYL COMPOUNDS 523
*2.7.3.1 Imidoyl Halides* 523
*2.7.3.1.1 From amides, thioamides and halogenating reagents* 523
*2.7.3.1.2 From isonitriles, nitriles and ketene imines* 526
*2.7.3.1.3 From imines by oxidation* 527
*2.7.3.1.4 From amines and haloalkanes or haloalkenes* 527
*2.7.3.1.5 From imidoyl halides* 527
*2.7.3.1.6 Miscellaneous methods* 528
*2.7.3.2 Imidates (Imidic Acid Esters, Imido Esters, Imidoates)* 529
*2.7.3.2.1 From alkoxymethyleneiminium salts or nitrilium salts* 529
*2.7.3.2.2 From imidoyl halides and related compounds* 532
*2.7.3.2.3 From carboxylic orthoesters, carboxylic orthoamide derivatives and related compounds* 533
*2.7.3.2.4 From nitriles and isonitriles* 533
*2.7.3.2.5 From imidates* 534
*2.7.3.2.6 Miscellaneous methods* 535
*2.7.3.3 Thioimidates* 536
*2.7.3.3.1 From alkylmercaptomethyleneiminium salts* 536
*2.7.3.3.2 From imidoyl halides* 539
*2.7.3.3.3 From nitriles and isonitriles* 540
*2.7.3.3.4 From activated aromatic compounds, alkenes, carbanions and carbenes* 540
*2.7.3.3.5 From thioimidates* 541
*2.7.3.3.6 Miscellaneous methods* 542
*2.7.3.4 Amidines* 542
*2.7.3.4.1 From iminium salts* 542
*2.7.3.4.2 From carboxylic acids or carboxylic acid amides and amines in the presence of condensing agents* 545
*2.7.3.4.3 From nitriles, isonitriles, ketene imines, carbodiimides and cyanamides* 546
*2.7.3.4.4 From 1,1-dihaloalkenes or ynamines* 550
*2.7.3.4.5 From imidoyl compounds* 550
*2.7.3.4.6 From orthoesters, orthoamides and related compounds* 553
*2.7.3.4.7 Miscellaneous methods* 554

2.7.4 CARBOXYLIC ORTHOACID DERIVATIVES 556
*2.7.4.1 Carboxylic Orthoesters* 556
*2.7.4.1.1 From 1,1,1-trihaloalkanes, α,α-dihalo ethers, haloalkenes, ketene acetals and alkoxyalkynes* 556
*2.7.4.1.2 From esters and diols or epoxides* 560
*2.7.4.1.3 By oxidation of carbonyl compounds and derivatives* 561
*2.7.4.1.4 From carboxonium salts, alkoxymethyleneiminium salts and related compounds (including amide acetals)* 561
*2.7.4.1.5 From orthocarbonic esters and related compounds (including trialkoxycarbenium ions)* 562
*2.7.4.1.6 From orthoesters* 563
*2.7.4.1.7 Miscellaneous methods* 564
*2.7.4.2 2,2-Bis(dialkoxy)carbonitriles* 564
*2.7.4.2.1 From orthoesters, ketene* O,O*-acetals and cyanating reagents* 564
*2.7.4.2.2 From dialkoxyhalomethanes or dialkoxycarbenium salts* 565
*2.7.4.2.3 Dehydration of 2,2-dialkoxycarboxylic acid amides* 566
*2.7.4.3 Amide Acetals (Including Lactam Acetals)* 566
*2.7.4.3.1 From amide halides (halomethyleneiminium salts)* 566
*2.7.4.3.2 From alkoxymethyleneiminium salts* 567
*2.7.4.3.3 From amidinium salts* 568
*2.7.4.3.4 By acetalization of amides; by addition reactions to nitriles, lactim ethers or* N*-acylimino esters* 569
*2.7.4.3.5 From orthoesters and related compounds* 570
*2.7.4.3.6 From orthoamide derivatives and related compounds* 571
*2.7.4.3.7 Miscellaneous methods* 572
*2.7.4.4 2-Alkoxy-2-dialkylaminocarbonitriles* 573
*2.7.4.4.1 From amide acetals and cyanating reagents* 573
*2.7.4.4.2 From alkoxymethyleneiminium salts and alkali metal cyanides* 573
*2.7.4.4.3 From alkoxydialkylaminoacetonitriles* 574
*2.7.4.5 Aminal Esters (Bis(dialkylamino)alkoxyalkanes)* 574
*2.7.4.5.1 From 1,1,1-trihaloalkanes or orthoesters* 574
*2.7.4.5.2 From acid amides, lactamidines and cyclic imino esters* 575
*2.7.4.5.3 From amidinium salts and related compounds* 575
*2.7.4.5.4 From orthoamide derivatives and related compounds* 576
*2.7.4.5.5 Miscellaneous methods* 577
*2.7.4.6 2,2-Bis(dialkylamino)carbonitriles* 577
*2.7.4.6.1 From 2,2-dihalocarbonitriles and amines* 577
*2.7.4.6.2 From secondary amines and hydrocyanic acid* 577
*2.7.4.6.3 From ketene aminals, aminal esters and tris(dialkylamino)alkanes* 577
*2.7.4.6.4 From amidinium salts and alkali metal cyanides* 578
*2.7.4.6.5 From 2-alkoxy-2-dialkylaminocarbonitriles and related compounds* 578
*2.7.4.6.6 Miscellaneous methods* 579
*2.7.4.7 Tris(dialkylamino)alkanes* 579
*2.7.4.7.1 From 1,1,1-trihaloalkanes, amide halides and related compounds* 579

*2.7.4.7.2 From amides, amidines and imidates* 579
*2.7.4.7.3 From amide halides and related compounds* 580
*2.7.4.7.4 From amidinium salts or 2,2-bis(dialkylamino)carbonitriles* 580
*2.7.4.7.5 From orthoesters, orthoamides and related compounds* 581
*2.7.4.7.6 From guanidinium salts or orthocarbonic acid derivatives* 582
*2.7.4.7.7 From ketene aminals* 582
*2.7.4.7.8 Miscellaneous methods* 583
2.7.5 REFERENCES 583

## 2.7.1 INTRODUCTION AND SCOPE

This chapter deals with 'activated amides', *i.e.* salt-like compounds, imino derivatives of carboxylic acids as well as compounds which formally arise by complete esterification or amidation of carboxylic orthoacids.

Well known compounds of this type are Vilsmeier–Haack adducts, imino esters, amidines, carboxylic orthoesters, orthoamides *etc.*, which have proven their synthetic utility in thousands of reactions. As a consequence of the synthetic importance of these compounds, more or less extensive reviews are available for all of them.

There exists a series of compounds which can also be regarded as activated amides, *e.g.* α-haloenamines, ketene *O,N*-acetals, ketene aminals or ynamines, which are not dealt with in this chapter. To show the scope of the contribution, the formulae of all the types of compounds which are treated in the text, together with references of the relevant reviews are listed in Table 1.

## 2.7.2 SALT-LIKE COMPOUNDS (IMINIUM SALTS)

### 2.7.2.1 Adducts from Amides (Thioamides) and Acylating Reagents

### *2.7.2.1.1 Phosphorus oxychloride and phosphorsulfur trichloride*

In preparative organic chemistry adducts from *N*-formylamines, *e.g.* *N*-methylformanilide and *N,N*-dimethylformamide, and $POCl_3$, which are used to formylate activated aromatic compounds and alkenes, are very important.[4] For these purposes it is not necessary to isolate the amide/$POCl_3$ adducts; usually they are prepared *in situ*. As a consequence of this only a few acid amide/$POCl_3$ adducts have been prepared in the pure state; examples are the adducts of $POCl_3$ with *N*-methylformanilide and *N,N*-dimethylformamide.[5] Elemental analysis revealed that adduct formation takes place in a 1:1 ratio. There has been much confusion on the constitution of these compounds.[1–5,7] There is no doubt that in solution adduct formation proceeds *via* attack at the carbonyl oxygen of the amide. This primary product (**1**) reacts further to give a salt (**2**) consisting of a chloromethyleneiminium ion with dichlorophosphate as the counterion (equation 1).

In formylation reactions both types of iminium compounds may act as electrophilic reagents. It has been demonstrated that the DMF–$POCl_3$ adduct is more reactive in formylation reactions than *N,N*-dimethylchloromethyleniminium chloride, which has the same cation. This indicates that the more reactive primary adduct from DMF and $POCl_3$ is the formylation species. But this conclusion is not fully convincing, because ion pair formation may take place in different amounts, meaning that in iminium chlorides there are more ion pairs than in the corresponding dichlorophosphates. Many reactions are known in which $POCl_3$ is used as a condensating agent, which indicates that there are adducts formed which act as reactive intermediates. From such experiments one may conclude that nearly all types of amides form adducts with $POCl_3$. Some examples of amides used in such reactions are: formamide, *N*-monosubstituted formamides,[5] *N,N*-disubstituted formamides,[4,5,7]· *N*-monosubstituted acetamides,[39,40] *N,N*-disubstituted acetamides,[41–44] mono- and di-substituted propionamides,[39,45] chloroacetamides,[39,46] phenylacetamides,[45] monosubstituted[40] and disubstituted[41] isobutyramides, malono ester amides,[47–54] cyanoacetamides,[45,55,56] *N*-monosubstituted[40,46,57] and disubstituted[41,46,58–60] benzamides, secondary aromatic[61] and higher aliphatic amides[61] as well as secondary[46] and tertiary[46,60] heterocyclic carboxamides, acylhydrazides[62–66] and lactams.[4,5,67–76]

**Table 1**

| *Formula* | *Type of compound* | *Ref.* |

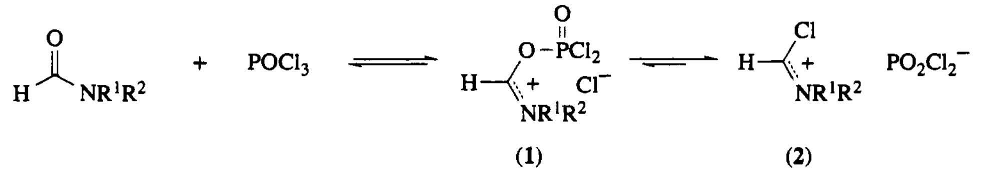
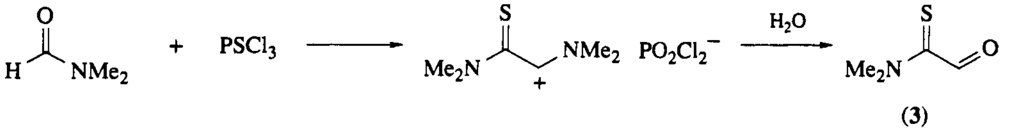
|  | 2,2-Bis(dialkylamino)carbonitriles | 7, 28, 29, 35 |
|  | Tris(dialkylamino)alkanes | 6, 7, 24, 28, 32, 35 |



(1)

(1) (2)

The adducts have been used for preparation of heterocyclic compounds,[4,5,37,46–48,52–54,56,59,63] in Beckmann rearrangement,[43] for cyclizations,[4,5,38,40,44,45,57,62,64,66,68] (a review covering cyclizations under Vilsmeier–Haack conditions is available[77]), for preparation of amidines,[5,7,39,41,42,55,76] in von Braun degradation,[61] in rearrangements,[68] in condensation reactions,[69] in substitution of aromatic compounds,[4,6,7,71,74] in reduction of amides,[72] in amide dimerization[73] and for preparation of isonitriles.[5] The adduct from DMF and $POBr_3$ was used for similar purposes.[4,5,7,78–81] The adduct formation either from thioamides and $POCl_3$ or amides and $PSCl_3$ has been studied.[82] The adduct of *N*,*N*-dimethylthioformamide with $POCl_3$ is said to be more reactive than the oxygen analog adduct.[4,5,7] It has been demonstrated that DMF undergoes selfcondensation with $PSCl_3$ to give *N*,*N*-dimethylglyoxylicthioamide (**3**) on hydrolysis (equation 2).[5]

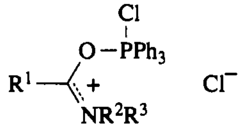


(2)

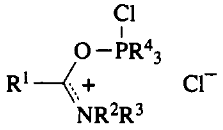
(3)

For preparative purposes it should be kept in mind that the use of these adducts, *e.g.* for C—C bond forming reactions,[1–4,6,83] can be restricted by several side reactions,[84] depending on the structure of the adducts. *N*,*N*-Unsubstituted adducts can decompose to nitriles by loss of HCl and $HOPOCl_2$ (this procedure was often used to prepare nitriles from amides[5,85–87]). *N*-Monosubstituted amides can split off $HOPOCl_2$ giving imidoyl chlorides (a reaction which is a standard procedure in heterocyclic chemistry, whenever a CONH unit is to be converted into a CCl═N unit); the imide chlorides thus formed on heating can lose alkyl chlorides—a process which is well known as von Braun degradation.[1–3,5,61] Adducts of *N*-monosubstituted formamides, especially in the presence of bases, furnish isonitriles by elimination of HCl and $HOPOCl_2$. This reaction is a very important method for the preparation of isonitriles.[1,5,88–97] Finally adducts derived from tertiary carboxamides, with $CH_2$—, or at least CH—, groups in the α-position to the amide function, can undergo selfcondensation, yielding products which can be regarded as adducts of $POCl_3$ with 2,3-disubstituted 3-chloroacrylic acid amides, which after hydrolysis afford β-keto acid amides.[1–5,7] In other cases heterocycles have been prepared by this type of condensation.[4,98]

Acid amide–triphenylphosphine dihalide adducts (**4**) have found wide application in organic synthesis.[5,7] Synthetic equivalents are adducts (**5**) from acid amides and triphenylphosphine/$CCl_4$, which are prepared *in situ* from the educts.[5,7] With these reagents the following transformations have been performed: dehydration of amides or aldoximes to nitriles, preparation of isonitriles from secondary formamides, preparation of imidoyl halides from amides or acylhydrazines and preparation of ketene imines from amides. Using polymer-supported triphenylphosphine the work-up procedure is much easier to achieve.[99] Triphenylphosphine can be replaced by tris(dialkylamino)phosphines.[5,7] Instead of $CCl_4$ hexachloroethane, hexabromoethane or 1,1,2,2-tetrabromo-1,2-dichloroethane can be used;[100] the adducts thus formed are assumed to be more effective than those from the triphenylphosphine/$CCl_4$ system.

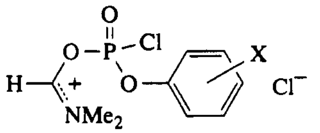


**(4)**

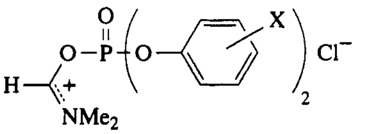


**(5)**

Adducts (**6**) and (**7**) from amides and chlorophosphoric acid aryl esters or dichlorophosphoric acid aryl esters respectively are well known.[5,7] The adducts are formed in a 1:1 ratio. They have been applied to the synthesis of mixed anhydrides from diarylphosphoric acids and carboxylic acids, as well as mixed substituted esters of pyrophosphoric acid. The adduct formation between primary or secondary carboxamides and dichlorophosphates has been used to prepare nitriles and isonitriles respectively.[5] The adduct from DMF and phenyldichlorophosphate is a useful reagent for the preparation of: carboxylic acid esters from the corresponding acids and alcohols,[101] β-lactams from imines and carboxylic acids,[102] carboxylic acid anhydrides,[103] carboxylic acid esters and thiol esters.[103] Adducts of amides with ester amides or diamides of chlorophosphoric acid have been studied.[103,104]

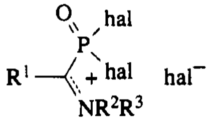


**(6)**

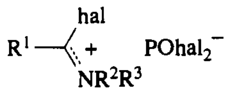


**(7)**

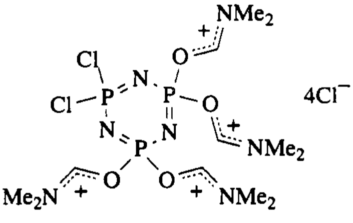
A still unresolved problem is the structure of the often used adducts from phosphorus trihalides and carboxylic acid amides, which might be described by the formulae (**8**) or (**9**). With the aid of *in situ* generated adducts of acid amides and $PX_3$ amidines,[5,7] isonitriles,[5] quinazolinones,[105] alkyl chlorides,[5] aminomethylenediphosphonic acids,[5,106] carbamoyl halides,[5] triformylaminomethane,[5,7] 1,3,4-oxadiazoles,[107] sulfides (from sulfoxides),[108,109] nitriles (from primary nitro compounds)[110] and bromoquinolines (from methoxyquinolines)[111] have been prepared.



**(8)**



**(9)**



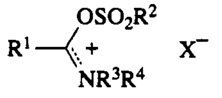
**(10)**

The adduct of DMF and dichlorophenylphosphine has been used to convert primary aromatic amides to nitriles by dehydration,[112] as well as to synthesize 2,5-diaryl-1,3,4-oxadiazoles from *N,N'*-diacylhydrazides.[113]

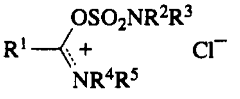
Phosphorus nitrile chloride forms adduct (**10**) with DMF in the ratio 1:4, which is useful for the preparation of formamidines and azavinylogous formamidinium salts.[5] It is supposed that the dehydration of primary amides to nitriles with $(PNCl_2)_3$ as well as the formation of 2-alkylbenzothiazoles from 2-(methylthio)anilides and $(PNCl_2)_3$ in the presence of triethylamine proceed *via* similar adducts.[114]

### *2.7.2.1.2 Adducts from acid amides and sulfur compounds*

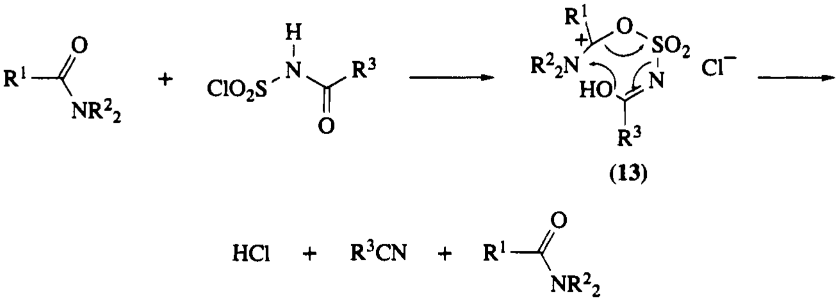
Sulfonyl halides (*e.g.* benzenesulfonyl chloride) form adducts (**11**) with acid amides in an equilibrium reaction.[5] From these adducts or *via* adducts of this type *O*-sulfonated lactim ethers, isonitriles, adenine, nitriles, amidines, amidinium salts and formic acid esters were prepared.[5] The adducts from DMF and chlorosulfonamides (**12**) can be used to prepare amidines or amidrazones.[5] *N*-Chlorosulfonylcarboxylic acid amides yield nitriles on treatment with DMF or other tertiary amides, presumably *via* an acid amide sulfonyl chloride complex (**13**; equation 3).[5]



**(11)**



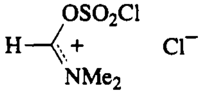
**(12)**



**(13)**

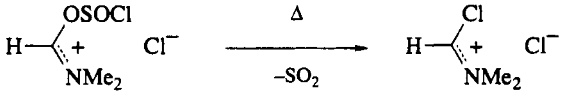
(3)

In contrast to these adducts the DMF–sulfuryl chloride adduct (**14**) has been prepared in a pure state.[5,7] It thermally decomposes to *N*,*N*-dimethylcarbamoyl chloride.[5] Secondary formamides form similar adducts, which on heating afford isocyanates.[5] Aromatic compounds such as anisole are not formylated by the DMF–$SO_2Cl_2$ adduct but chlorosulfonated.[5] This reaction was also performed with thiophenes; 2-thiophenecarbaldehydes are formed as byproducts.[115] The formation of triformaminomethane from formamide and $SO_2Cl_2$ has been reported.[5]



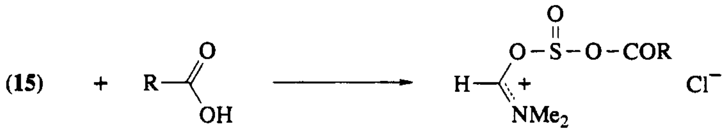
**(14)**

Thionyl chloride forms a fairly stable primary adduct (**15**) with DMF, which has been isolated.[5,7] On heating it decomposes to $SO_2$ and *N*,*N*-dimethylformamide chloride (equation 4).[5] Treatment of the adduct (**15**) with carboxylic acids affords iminium salts (**16**; equation 5) in which the carboxylic acid function is strongly activated, *e.g.* for amide formation.[116] With imines β-lactams are formed, sodium azide is converted to acyl azides.[117]



**(15)**

(4)

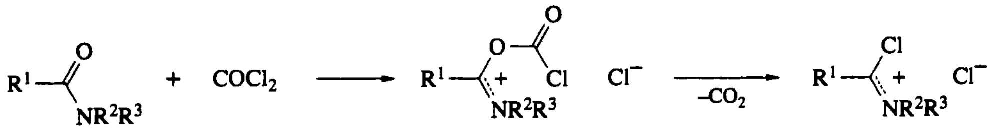


**(16)**

(5)

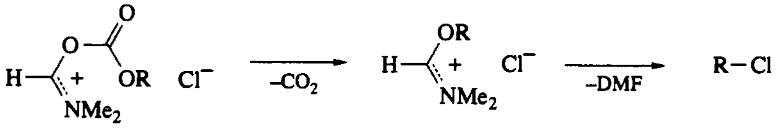
### 2.7.2.1.3 *Adducts from amides and carbonic acid derivatives*

Phosgene and tertiary carboxylic acid amides form very labile adducts (**17**; equation 6; not yet isolated or used for preparative purposes as such), which decompose with loss of $CO_2$ very rapidly to give amide chlorides (see Section 2.7.2.2.1.i). Decomposition with evolution of $CO_2$ is a common fate of primary adducts of carbonic acid chloride derivatives. Primary adducts from DMF and chloroformic acid esters (**18**), for example, decompose immediately to give alkoxymethyleneiminium chlorides, which react to give alkyl chlorides and DMF (equation 7).[5,118] Adducts (**19**) from secondary and tertiary carboxamides and *N*,*N*-dialkylcarbamoyl chlorides are formed at elevated temperatures (about 120 °C). However, under these conditions the adducts thus formed decompose to yield amidinium salts (equation 8).[5]



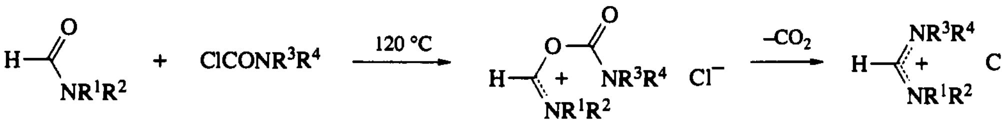
(6)

**(17)**



(7)

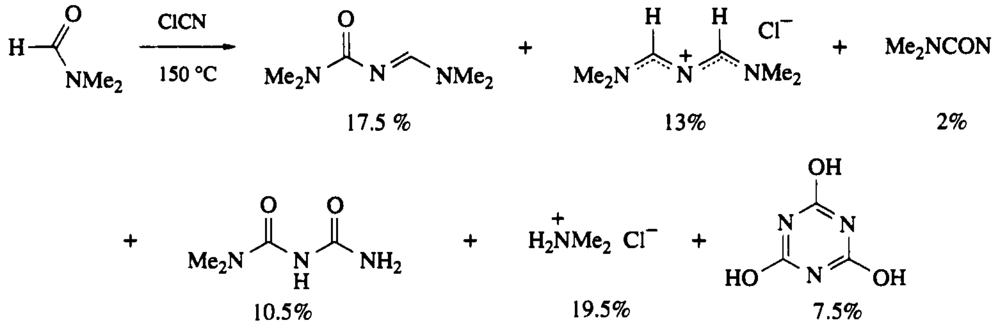
**(18)**



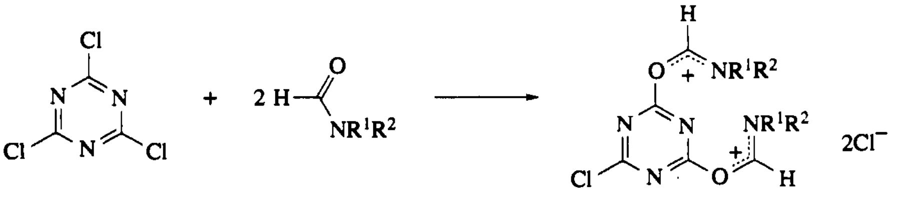
(8)

**(19)**

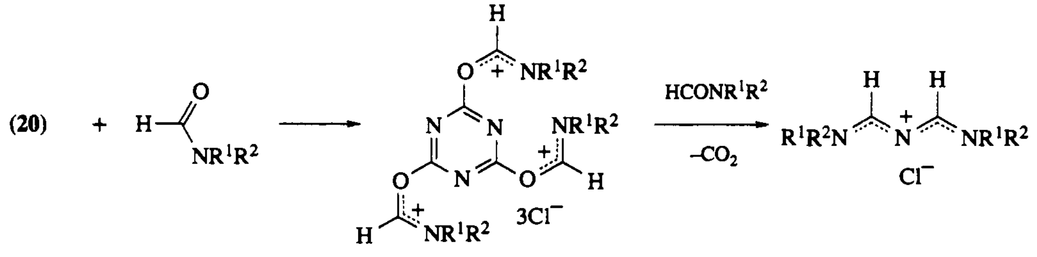
Adduct formation between cyanogen chloride and DMF was proposed to explain the complex product mixture, which was obtained by reaction of these educts at 150 °C (equation 9).[5] More important are adducts (**20**) from cyanuric acid chloride and tertiary formamides. These compounds are formed in a 1:2 ratio and they are isolable when DMF or *N*-formylpyrrolidine is used.[5,121] The adducts have been used to formylate ketones at the α-$CH_2$ groups,[122] sterically hindered phenols can be formylated at the oxygen,[123] amides are dehydrated to nitriles[124] and secondary formamides are transformed to isonitriles.[5] Using these adducts, amidines,[5] *N*-acylamidines,[123] alkyl halides[5] and amidinium salts[5] have been synthesized. In the preparation of these adducts an excess of amide must be avoided, because the 2:1 adducts (**20**) react with further tertiary formamide to give a labile, not isolable 1:3 adduct (**21**; equation 11), which, in the presence of excess amide, decomposes with great ease with evolution of $CO_2$ to give azavinylogous formamidinium salts.[5] The mechanism of this complex reaction has been established.[125]



(9)



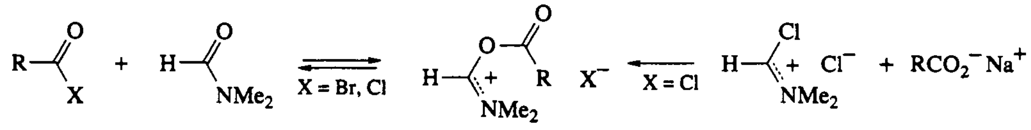
(10)



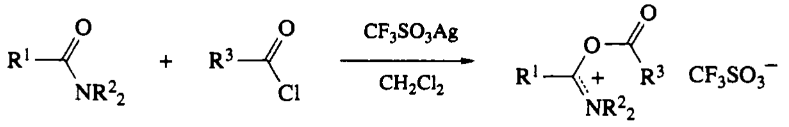
**(21)** (11)

### *2.7.2.1.4 Adducts from acid amides and carboxylic acid derivatives*

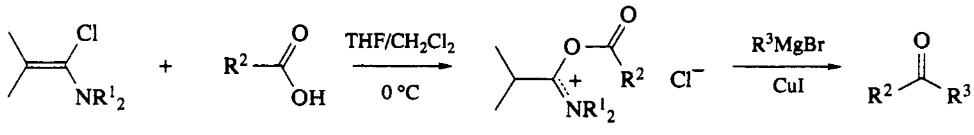
Conductivity measurements have revealed that DMF and carboxylic acid chlorides form salt-like adducts (**22**) in an equilibrium reaction (equation 12).[5,7] Such adducts can be prepared either from DMF and acid halides (chlorides and bromides)[5] or from chloromethyleneiminium salts and salts of carboxylic acids.[5,126] Acyloxyiminium salts (**23**) can be prepared in the pure state by reacting acid amides with carboxylic acid chlorides in the presence of silver trifluoromethanesulfonate (equation 13).[127] Salts of type (**24**; equation 14) are regarded as being intermediates in the synthesis of ketones from carboxylic acids and Grignard reagents in the presence of α-chloroenamines[128] as well as in the preparation of acyl halides (F, Cl, Br, I) by action of α-haloenamines on carboxylic acids.[129]



**(22)** (12)



**(23)** (13)



**(24)** (14)

Acid amide–acid halide adducts have been used in synthetic organic chemistry to prepare various types of compounds (see Table 2).

Crystalline adducts from thioamides and aromatic acid chlorides are well known.[5] A very convenient synthesis of diacyl sulfides[139] and thiocarboxylic acids[139,140] proceeds *via* adducts of thio-DMF with acid chlorides.

From formylation reactions of CH-acidic compounds, which take place if mixtures of carboxylic acid amides and anhydrides are used as formylating agents, it was concluded that the latter compounds form similar adducts to those from amides and acid halides.[5]

**Table 2** Preparative Applications of Acid Amide–Acid Chloride Adducts

| *Starting amides* | *Ref.* | *Products* | *Ref.* | *Products* | *Ref.* |
|---|---|---|---|---|---|
| Formamide | 5, 130 | Formimino ester hydrochlorides | 5 | Tris(1-methyl-3-indolyl)methane | 132 |

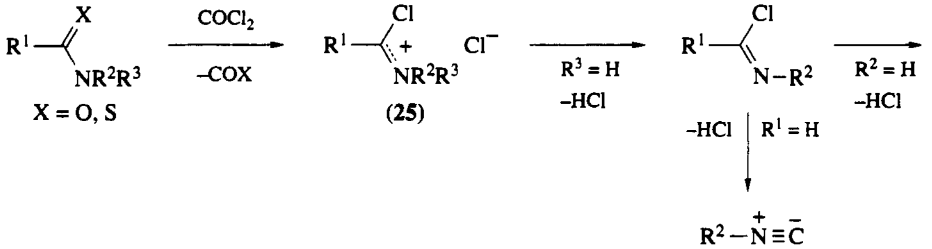
## 2.7.2.2 Halomethyleneiminium Salts (Amide Halides)

### *2.7.2.2.1 From halogenating reagents and acid amides*

*(i) Phosgene, diphosgene, carbonyl dibromide, carbonyl difluoride, oxalyl dihalides*

Phosgene, as well as the easier to handle 'diphosgene' (chloroformic acid trichloromethyl ester)[141] or 'triphosgene' (carbonic acid bis(trichloromethyl) ester) transform primary, secondary and tertiary amides and thioamides to chloromethyleneiminium chlorides (**25**; equation 15),[1,7–9] whereby the reaction with thioamides is of broader scope and proceeds with fewer side reactions. The amide chlorides derived from primary and secondary amides can lose HCl, giving nitriles or imidoyl halides, respectively.[9] *N*-Substituted formamides can be converted to isonitriles *via* amide halides.[9]



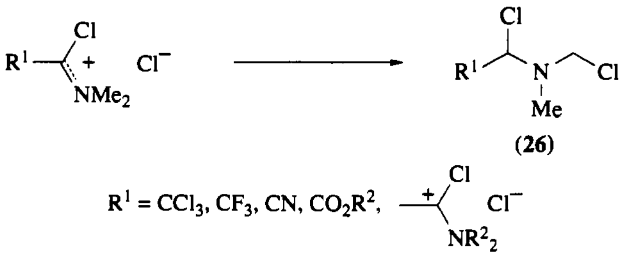
**(25)**

(15)

It should be noted that amide chlorides bearing strong electron acceptors (*e.g.* $CCl_3$, $CF_3$, CN, $CO_2R$, $ClCNMe_2$ groups) in the α-position readily undergo rearrangement to α,α′-dichloroamines (**26**; equation 16).[142–144] Oxalyl chloride has been used to prepare amide chlorides (*e.g.* **27**; equation 17) from tertiary amides; side reactions are known if α-halogenated amides or thioamides containing α-$CH_2$ groups are used in this reaction.[5] From carbonyl dibromide and tertiary carboxamides the corresponding bromomethyleneiminium salts (**28**; Scheme 1) were synthesized, which often possess $Br_3^-$ as a counterion from which $Br_2$ can be split off by treatment with cyclohexene.[7,9] The action of carbonyl difluoride on tertiary amides gives rise to formation of α,α-difluoroamines (**29**),[7,9,145] which seem to be dissociated only to a very small extent.[7,9,146,147]

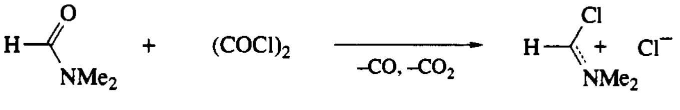
*(ii) Phosphorus compounds*

Wallach was the first (1874) to report on the transformation of carboxylic acid amides to amide chlorides by treatment with $PCl_5$;[7–9] various types of amides were converted by this reagent to chloromethyleneiminium chlorides (**30**; equation 18).[7–9,148,149] Side reactions can include the α-chlorination of the amide chloride.[8,9] If excess $PCl_5$ is used, the formation of iminium salts with complex ions (**31**) has been reported.[150] The very labile bromomethyleneiminium bromides (**32**; equation 19) can be obtained by action of $PBr_5$ on tertiary amides.[7,9] The iodomethyleneiminium salt (**33**) was prepared from DMF and diphosphorus tetraiodide in $CS_2$.[151]



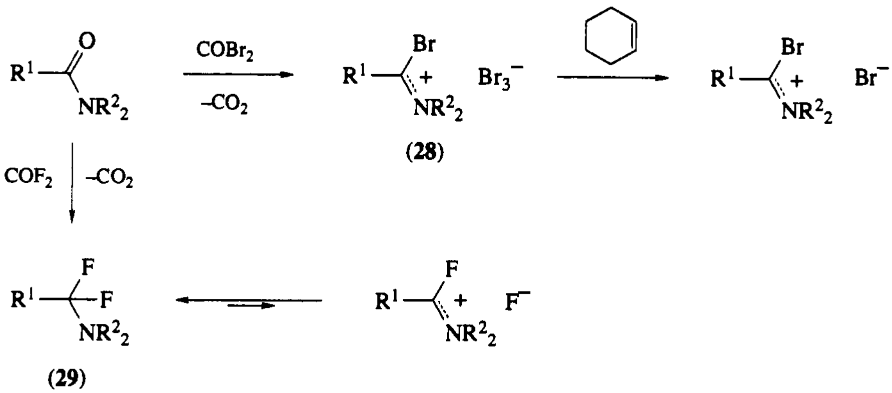
**(26)**

(16)

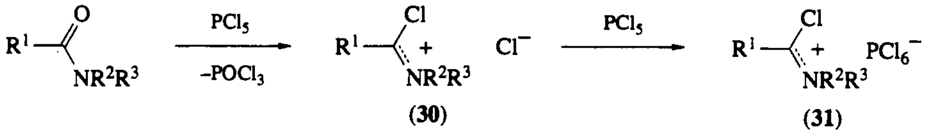


**(27)**

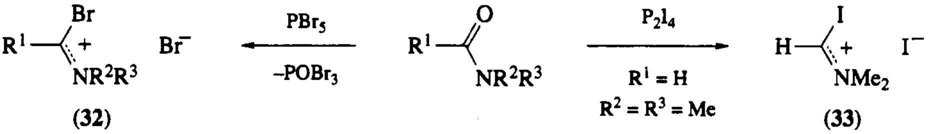
(17)



Scheme 1



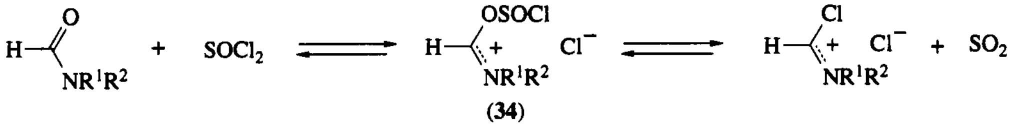
(18)



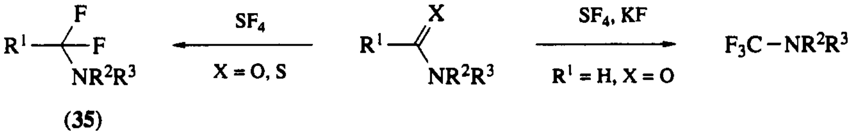
(19)

*(iii) Sulfur compounds*

Thionyl chloride was often used to synthesize amide chlorides from amides. The mechanism of this reaction has been thoroughly studied.[9] According to these investigations a primary adduct is formed (**34**; equation 20), which loses $SO_2$ in a reversible reaction to give the amide chloride (compare Section 2.7.2.1.2).[9] Mixtures of $SOCl_2$ with $PCl_5$ have also been used to convert amides to amide chlorides.[152] Amide fluorides (α,α-difluoroamines) (**35**; equation 21) can be obtained by the action of sulfur tetrafluoride on amides[7,9,153] or thioamides.[9,154] In the presence of KF tertiary formamides react with $SF_4$ to give α,α,α-trifluorodialkylamines.[155]



(20)

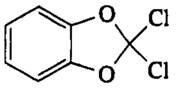


(21)

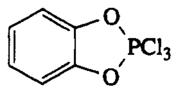
*(iv) Miscellaneous reagents*

A very efficient preparation of amide chlorides comprises the action of elemental chlorine on thioamides in $CH_2Cl_2$ or $CCl_4$; even amide chlorides which possess electron-attracting substituents in the α-position have been prepared in this way.[7,9,143,156]

DMF was converted to the corresponding iminium salt (**27**) by the following reagents:[5] perfluorobutyryl chloride, 2,2-dichlorobenzodioxole (**36**) and 2,2,2-trichlorobenzodioxaphosphole (**37**).



**(36)**

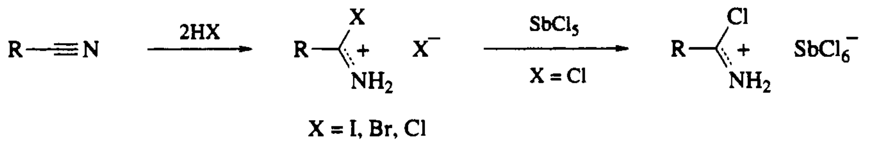


**(37)**

### 2.7.2.2.2 By addition reactions

#### (i) Hydrogen halides to nitriles or imidoyl halides

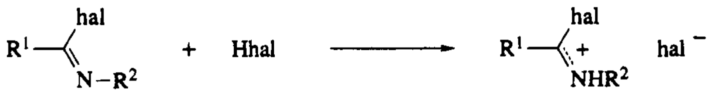
The formation of amide chlorides from nitriles and hydrogen halides under anhydrous conditions is a well-known reaction of wide scope.[7,9] There has been some confusion on the nature of the reaction products, but it has turned out that the isolable species are amide chlorides. The thermal stability of the addition products strongly depends on the acidity of the hydrogen halide used. Iodides are more stable than bromides, which in turn are more stable than the chlorides. As a consequence, thermally stable HCl adducts (**38**; equation 22) can be prepared if Lewis acids are present, which incorporate the chlorine anion to give a less basic anion (**39**).



**(38)** **(39)** (22)

The reaction of fluorinating reagents such as $F_2$,[157] $HgF_2$,[158] $CoF_3$[159] and $AgF_2$,[159] in the presence of halogens[158] or interhalogen compounds,[157] with nitriles produces *N*-halogenated amide fluorides (*e.g.* **40** and **41**; equation 23). *N*-Alkylated imidoyl halides add HCl or HBr to give the corresponding iminium salts (**42**; equation 24).[7,9]

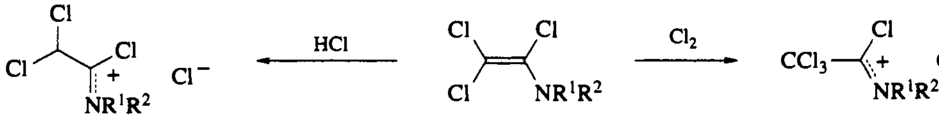
$$\underset{\mathbf{(40)}}{RCF_2NClF} \xleftarrow{F_2,\ ClF} R{\equiv}N \xrightarrow{Cl_2,\ HgF_2} \underset{\mathbf{(41)}}{RCF_2NCl_2} \qquad (23)$$



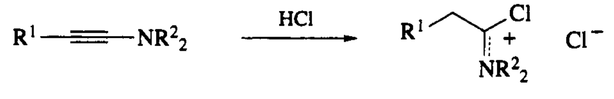
**(42)** (24)

#### (ii) Hydrogen halides or halogens to α-chloroenamines or ynamines

Hydrogen halides (*e.g.* HCl) or halogens (*e.g.* $Cl_2$) add to chloroenamines to give amide chlorides (**43** and **44**; equation 25). The HCl addition seems to proceed reversibly.[9] By addition of HCl or $Cl_2$ to ynamines the iminium salts (**45**; equation 26) and (**46**; equation 27) were synthesized.[9,143]

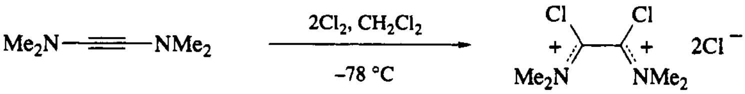


**(43)** **(44)** (25)



(45)

(26)

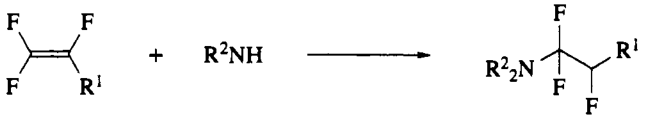


(46)

(27)

*(iii) Amines to 1,1-dihalogenated alkenes*

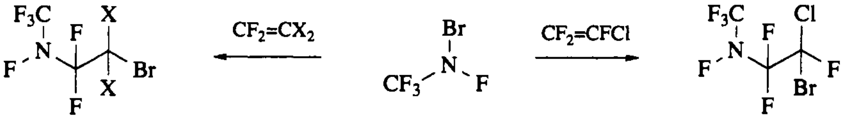
Perfluoroalkenes[9,160] and perfluorinated chloroalkenes[161] add secondary amines to give α,α-difluoroamines (**47**; equation 28). The *N*-halogenated amine (**48**) reacts with perhalogenated alkenes in a similar fashion. (equation 29).[162]



$R^1$ = F, CF$_3$

(47)

(28)



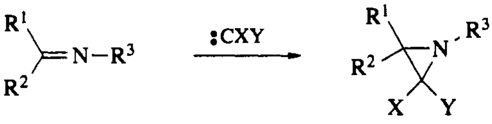
X = F, Cl, Br

(48)

(29)

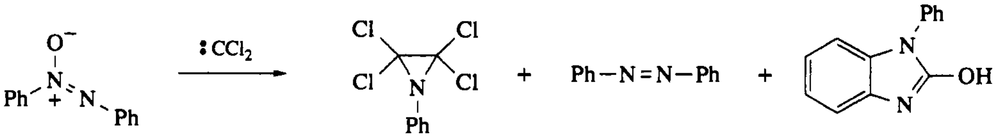
*(iv) Dihalocarbenes to C═N group containing compounds*

Dihalocarbenes generated from haloforms and strong bases (*e.g.* alkoxides) or from haloforms and alkali metal hydroxides under phase transfer conditions[9,163–165] or organomercurytrihalomethanes,[9] add to azomethines to yield 2,2-dihaloaziridines (**49**; equation 30). The following carbenes have been used for such purposes: dichlorocarbene,[1,9,163–168] dibromocarbene,[165–167] difluorocarbene,[169,170] bromochlorocarbene[167] and bromofluorocarbene.[167] The addition of dihalocarbenes to azoxybenzene[9,171] or azobenzene affords dihaloaziridines (*e.g.* **50**; equation 31) among other products.



(49)

(30)



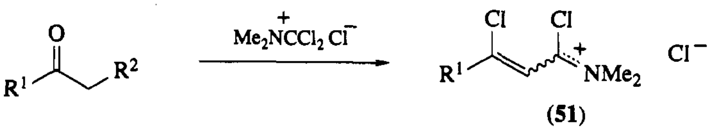
(50)

(31)

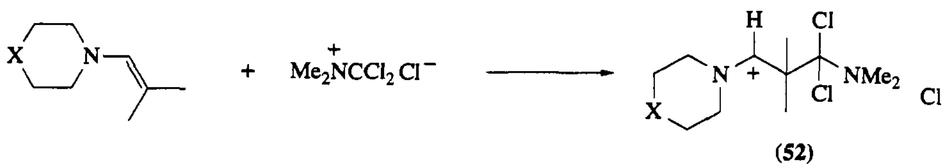
### 2.7.2.2.3 *From dihalomethyleneiminium salts (phosgene iminium salts, PI salts)*

Dihalomethyleneiminium salts undergo condensation reactions with CH-acidic compounds such as ketones, carboxylic acid chlorides, nitriles and amides, to give amide halides, *e.g.* (**51**; equation

32).[7,9,172–174] Amide chlorides were obtained by the same method from enamines,[9,172] fulvenes,[175] barbituric acid derivatives[176] or pyridopyrimidines[177] and PI salts (*e.g.* **52**; equation 33).



(32)

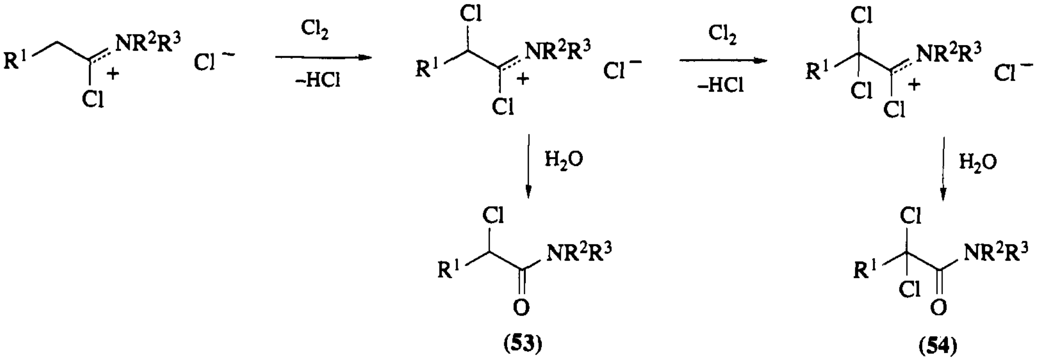


(33)

### 2.7.2.2.4 *From halomethyleneiminium salts*

*(i) By halogenation*

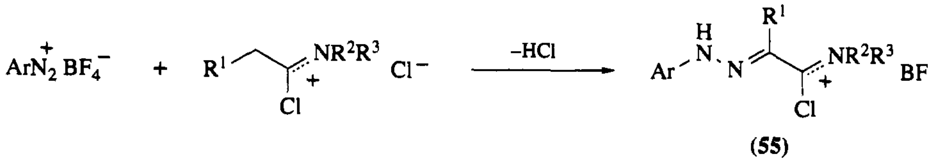
Amide chlorides which contain an α-CH or α-$CH_2$ group readily undergo chlorination in these positions. The amide chlorides thus formed were not isolated but their hydrolysis products, α-chlorinated amides (**53**) and (**54**; Scheme 2)[8,9,144] were formed.[8,9,144]



**Scheme 2**

*(ii) By diazocoupling*

In a few examples it was demonstrated that diazonium salts are capable of coupling with amide chlorides in the α-position yielding hydrazones of α-keto acid amide chlorides (**55**; equation 34).[8,9]



(34)

*(iii) By condensation with carbonyl compounds or by selfcondensation*

Although the selfcondensation of amide chlorides proceeds well to give amide chlorides derived from β-keto acids (**56**; equation 35) this reaction has only been used to synthesize β-keto acid amides, which result after hydrolysis of the condensation products (**56**), and not to prepare the salts (**56**) in the pure state. The condensation reaction of aromatic aldehydes with the *N*,*N*-dimethylacetamide–$POCl_3$ adduct in the presence of $HClO_4$ affords iminium salts (**57**; equation 36), which are hydrolyzed to cinnamic acid amides.[178]

*(iv) By halogen exchange or anion exchange reactions*

Both chlorines in the iminium chloride (**27**) can be replaced by fluorine, bromine or iodine, giving compounds (**58**)–(**60**) (Scheme 3) if the salt is treated with the corresponding hydrogen halide under anhydrous conditions.[7,9] By chloro–iodo exchange with HI from the 3-chloroacrylamide chloride the corresponding amide iodide (**61**; equation 37) was prepared.[179] Dimethylformamide chloride (**27**) is converted by methyl iodide to dimethylformamide iodide (**59**).[180] Remarkably the difluoro compound (**60**) is a nonionic, distillable liquid which can be ionized by addition of boron trifluoride.[9]

*(v) Miscellaneous methods*

Octafluoroisobutene reacts with phenyl azides, presumably *via* a triazole which loses nitrogen to give the difluoroaziridine (**62**; equation 38).[170] *N*-Aryltrichloroethylamines are cyclized to dichloroaziridines (**63**; equation 39) on treatment with potassium *t*-butoxide.[181] A related procedure is the reduction of trichloroacetophenone imines by $LiAlH_4$, which can be stopped at the stage of the dichloroaziridines (**64**; equation 40).[182] Triethylamine splits off hydrogen iodide from the iminium salt (**61**) to give the 2-propinylium iodide (**65**; equation 41).[179] With fluorosulfonic acid methyl ester the imidoyl chloride (**66**) was methylated to yield the iminium salt (**67**, equation 42).[183]

## 2.7.2.3 Alkoxymethyleneiminium Salts

### *2.7.2.3.1 From amides and alkylating reagents*

Fifty years ago Meerwein demonstrated that tertiary oxonium salts alkylate amides at the oxygen of the carbonyl group.[7,10] Since then a lot of amides have been converted by these reagents to the corresponding iminium salts (**68**; Scheme 4). The results show that there is little restriction in the use of this procedure. Only strongly electron-attracting groups eventually, in connection with high steric efficiency, are able to prevent the alkylation of the oxygen of the amide function. Thus *N*,*N*-dimethyltrichloroacetamide or *N*,*N*-dimethylcarbamoyl chloride do not react with triethyloxonium tetrafluoroborate.[10] If other functional groups are present in the amide molecule which are sensitive to strong alkylating reagents, *e.g.* orthoester structures,[10] thiadiazoline compounds,[184] amino groups *etc.*, they may also be attacked or degraded; however, there are known alkylations of 4-amino-5-aminocarbonylimidazolyl nucleosides at the oxygen of the amide function.[185] Steric effects alone seem not to be able to block the reaction as can be seen from the alkylation of isobutyramides[186] or pivalic acid dimethylamide.[10] No restrictions of the alkylation procedure are known either in the series of aromatic acid amides[7,10,187–189] or in the case of *N*,*N*-diaryl-substituted carboxylic acid amides. Triple bonds[10,190,191] and double bonds[10,192] can be present in the amide molecule.

Oxonium salts alkylate diamides of dicarboxylic acids twice, provided the amide groups are separated by at least two carbon atoms,[10,193,194] thus the bis(dimethylamides) of maleic acid or terephthalic acid have been converted to dications (**69**; Scheme 4) by means of oxonium salts.[10]

*N*-Acylimino compounds are converted by oxonium salts to iminium salts, which can be regarded as azaallenium salts.[195–198] A lot of lactams have been alkylated by oxonium salts at the carbonyl oxygen to give salts of type (**70**; equation 43).[7,10,199–207]

The action of oxonium salts on vinylogous amides affords iminium salts (**71**; equation 44), which are useful for synthetic purposes in heterocyclic chemistry.[10,208–211,214] Alkyldiphenylsulfonium tetrafluoroborates (**72**; equation 45) were recommended as reagents which alkylate amides and lactams under smooth conditions.[212] With the aid of fluorosulfonic acid esters[7,10,186,213] as well as with trifluoromethanesulfonic acid esters,[7,10,214,215] which have alkylation power comparable to oxonium salts, iminium salts, *e.g.* (**73**) and (**74**; Scheme 5), could be synthesized from amides,[186,214] vinylogous amides[213] and lactams.[215] Trimethylsilyloxymethyleneiminium salts (**75**; equation 46) are accessible by reacting trimethylsilyltrifluoromethanesulfonate with amides.[216,217]

Although carboxonium salts (**76**; equation 47) are easily available and of high alkylation power, they have found little application for alkylation of amide groups.[10]

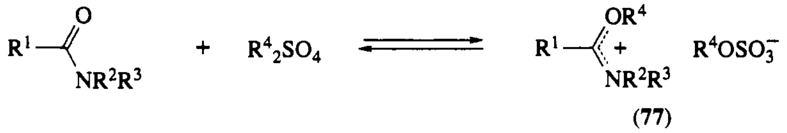
(47)

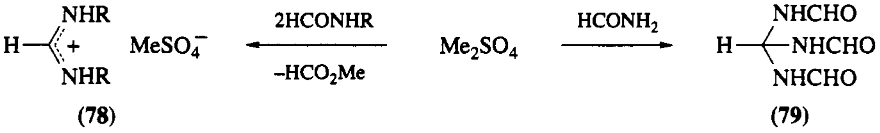
Dialkyl sulfates alkylate acid amides in an equilibrium reaction at the carbonyl oxygen to give iminium salts (**77**; equation 48).[7,10] The position of the equilibrium depends on the nature of the substituents: bulky and electron-attracting groups shift it to the starting compounds. Fortunately in the case of the most important iminium salts, derived from *N,N*-dialkylated formamides or acetamides, the position of the equilibrium is situated far on the side of the iminium compounds, so that this reaction is by far the most convenient way to produce salts derived from formamides and acetamides. The alkylation is slow at room temperature, it can be accelerated by heating the components up to 80 °C. Higher temperatures should not be applied in order to avoid side reactions. *N*-Monosubstituted formamides react with dimethyl sulfate in a molar ratio of 2:1, yielding *N,N'*-disubstituted formamidinium salts (**78**; equation 49); formamide itself reacts in a more complicated way to give tris(formylamino)methane (**79**).[10]



**(77)**

(48)

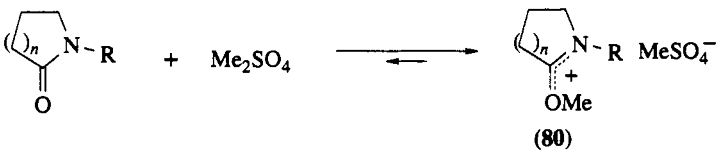
$R^1 = H$, alkyl ($C_1$–$C_5$), Ph, $PhCH_2$, $CH_2CONR_2$



**(78)** **(79)**

(49)

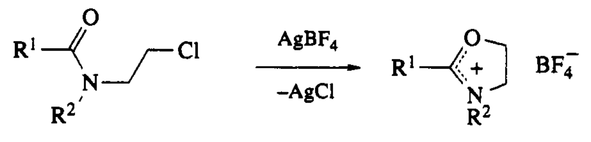
In the alkylation of lactams the equilibrium position also lies at the side of the iminium compounds (**80**; equation 50), so it is not surprising that 4- to 12-membered ring lactams have been methylated by dimethyl sulfate to produce the corresponding cyclic iminium salts.[10]



**(80)**

(50)

The alkylation of amides by alkyl halides or simple sulfonic acid esters is usually of little importance because the alkylation equilibrium is placed on the side of the starting compounds. This is not the case, however, in either the alkylation of vinylogous amides (which has been achieved even with alkyl iodides[218]) or if intramolecular alkylation is possible, *e.g.* in *N*-(2-haloethyl)amides. In the latter case cyclic iminium compounds (**81**; equation 51) are readily available by replacing the more nucleophilic halide by less nucleophilic complex anions, which can be achieved by addition of Lewis acids or $AgBF_4$.[10,219]



**(81)**

(51)

### 2.7.2.3.2 *From carboxylic acid amides and acylating reagents*

Primary and secondary amides and thioamides react with alkyl chloroformates with loss of $CO_2$ or COS, forming iminium chlorides (**82**; equation 52). In some cases this method is complementary to the Pinner imido ester hydrochloride synthesis.[7,10] The iminium salt (**83**; Scheme 6) formed by action of ethyl chloroformate on DMF is labile and decomposes rapidly to ethyl chloride. If the reaction is performed in the presence of $NaBF_4$, the iminium salt (**85**) is isolable. Aryl chloroformates react in the same fashion with DMF or DMA, but in these cases the aryloxymethyleneiminium compounds are fairly stable, so this reaction is an important method for the preparation of compounds of this type.[7,10] Succinic acid monoamides, phthalic acid monoamides and related compounds are cyclized to iminium salts (**86**; equation 53) by treatment with acetic anhydride and $HClO_4$.[220] With the aid of trifluoromethanesulfonic anhydride lactams and amides can be converted to dication ether salts (**87**) and (**88**; Scheme 7).[221,222]

(53)

### 2.7.2.3.3 *By alkylation or acylation of imino esters*

Alkylation and acylation of imino esters proceeds at the nitrogen of the imino ester function. In many cases it is not advisable to use alkyl halides or acyl halides for such reactions because the iminium salts (**89**) or (**90**; Scheme 8) are readily dealkylated by the halide anions. This can be prevented by the use of stronger alkylating reagents, *e.g.* tertiary oxonium salts, dialkyl sulfates or alkyl triflates, which produce in the course of the alkylation only anions with low nucleophilicity.[10,223,224] Heterocycles containing

#### 2.7.2.3.4 *From halomethyleneiminium salts and related compounds*

The reaction of amide chlorides with alcohols to yield alkoxymethyleneiminium salts, *e.g.* (**91**) and (**92**; Scheme 9), is important for the preparation of cations with bulky alkoxy groups, *e.g.* $t$-butoxy. These alcoholysis reactions demand the presence of salts with less nucleophilic anions in order to avoid dealkylation of the cations. This difficulty does not arise if the iminium hexachloroantimonates, which are obtained from the chlorides by addition of SbCl$_5$, are used for alcoholysis.$^{7,10}$ A convenient route to $N$-unsubstituted salts (**93**; equation 54) is the alcoholysis of the formamide–benzoyl chloride adduct.$^{7,10}$ The reaction of phenols with dimethylformamide chloride (**27**) affords aryloxymethyleneiminium salts (**94**; equation 55) which are hard to prepare by other methods. By addition of alkynols to the $\alpha$-haloenamine (**95**) alkoxymethyleneiminium salts have been obtained (equation 56).$^{225}$

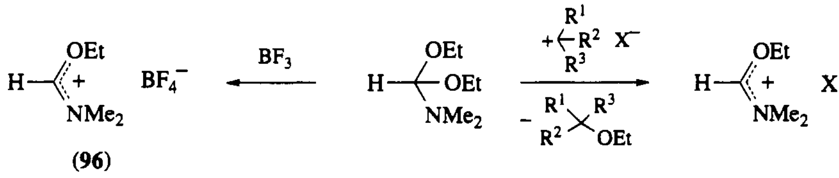
### 2.7.2.3.5 *From orthoamide derivatives and related compounds*

Strong Lewis acids abstract alkoxide groups from amide acetals or lactam acetals to give the corresponding iminium salts, *e.g.* (**96**; Scheme 10). Alkoxide transfer from amide acetals to less stable carbenium ions is also a route from amide acetals to iminium compounds (**97**).



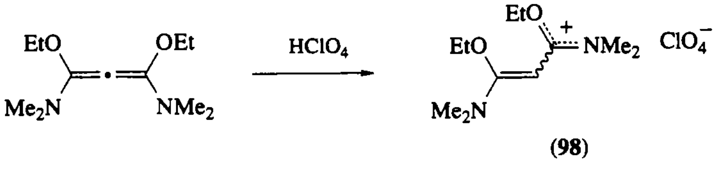
$R^1 = H, R^2 = R^3 = OEt; X = BF_4$ (**96**)

or $X = SbCl_6$ (**97**)

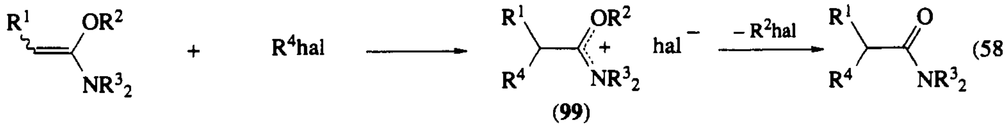
$R^1 = R^2 = R^3 = Ph; X = BF_4$

**Scheme 10**

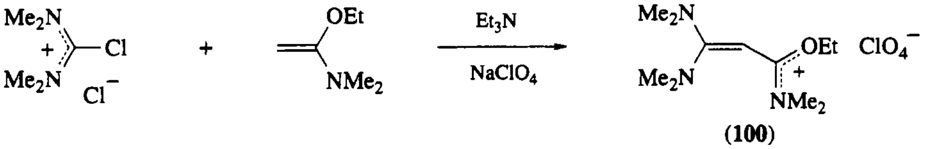
Protonation of ketene *O*,*N*-acetals with strong acids gives rise to the formation of iminium compounds, *e.g.* (**98**; equation 57). Ketene *O*,*N*-acetals are transformed by alkyl halides or acyl halides to α-substituted amides *via* unstable iminium salts (**99**; equation 58).[10] Iminium compounds of this type are isolable if they are immediately precipitated, *e.g.* as perchlorate salts (**100**; equation 59).[227] Heterocumulenes such as isocyanates,[10] isothiocyanates[10] or $SO_2$[226] form 1,4-dipoles with ketene *O*,*N*-acetals, which can be stabilized by protonation with perchloric acid to give salts, *e.g.* (**101**; equation 60).



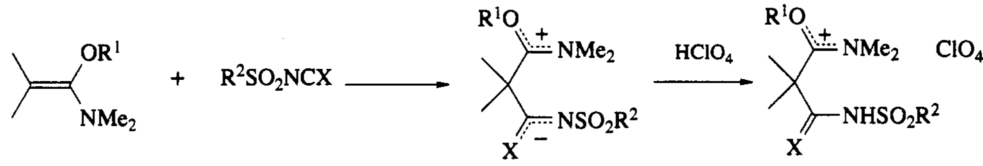
(57)



(58)



(59)

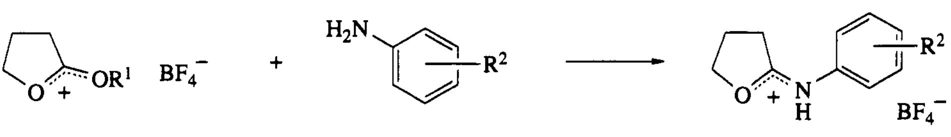


(60)

**(101)**

### 2.7.2.3.6 *From carboxonium salts*

Dialkylcarboxonium ions possess a very high alkylation power. If they are reacted with amines or amine derivatives, the substitution of the alkoxy group by the amino compound competes with the dealkylation of the carboxonium ion. Therefore only a few examples for the preparation of iminium salts are known, *e.g.* (**102**; equation 61), from carboxonium salts.[10,228,229]



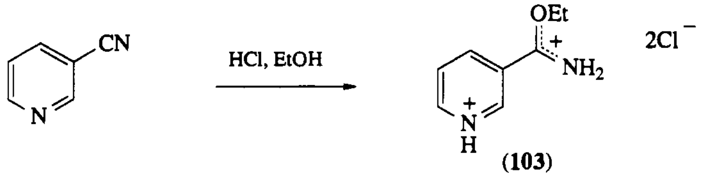
(61)

$R^2$ = 4-Me, 4-Cl, 2-$CO_2Et$

**(102)**

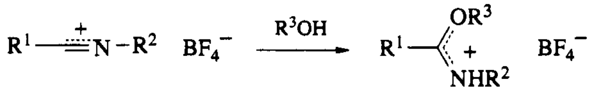
### 2.7.2.3.7 *From nitriles or nitrilium salts*

The addition of water-free alcohols to the nitrile group in the presence of HCl or HBr in a temperature range of 0–5 °C is a versatile synthesis for *N*-unsubstituted alkoxymethyleneiminium salts. Detailed reviews on these reactions have been published.[16,230,231] More recently it has been demonstrated that 'imido ester hydrochlorides' can be prepared, *e.g.* (**103**; equation 62), from heterocyclic nitriles[232,233] even if they have strong basic character.[232–234] The transformations of α-aryloxynitriles,[237] adamantanedicarbonitriles,[237] glycosidic-bound oxynitriles[238] and benzonitriles[239,240] with highly reactive functional groups, *e.g.* enol ether structures, to the corresponding imido ester hydrohalides have been described. Nitrilium salts add alcohols and phenols to give *N*-monosubstituted alkoxymethyleneiminium salts (**104**; equation 63).[7,10,241,242]



(62)

**(103)**

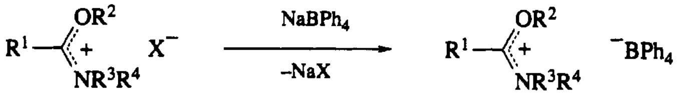


(63)

**(104)**

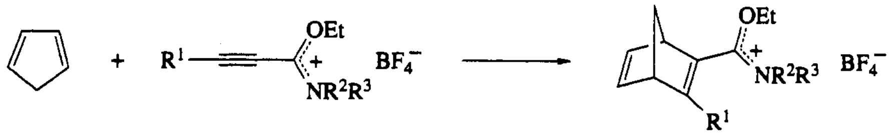
### 2.7.2.3.8 *Miscellaneous methods*

In alkoxymethyleneiminium salts the anions are exchangeable ($Cl^-$ *versus* $ClO_4^-$ or $SbCl_6^-$ *etc.*). This procedure can be used to purify the iminium compounds for analytical purposes. Tetraphenylborates (**105**), which are easy to obtain from the iminium salt and sodium tetraphenylborate in dry acetonitrile (equation 64), and which crystallize easily, are suitable reagents. The carbon skeleton of α,β-unsaturated alkoxymethyleneiminium compounds can be altered by cycloadditions, *e.g.* Diels–Alder reactions, to give compounds of type (**106**; equation 65).[7,10]



(105)

(64)



(106)

(65)

### 2.7.2.4 Alkylmercaptomethyleneiminium Salts

#### *2.7.2.4.1 From thioamides and alkylating reagents*
